Industrial Gauges.—The present article is limited primarily to a treatment of pressure gauges used industrially, with only mention of the broader variety of gauges used in scientific research and development.

The pressure element of the majority of mechanical pressure gauges is usually in one of three forms: a Bourdon tube; a corrugated diaphragm or diaphragm capsule; or a bellows. Of these the Bourdon tube type is the most common.

Bourdon Tube.—The Bourdon gauge is one in which the pressure is indicated directly by an attached pointer and scale. The

FIG. 1.—INTERNAL MECHANISM OF A BOURDON GAUGE

Bourdon tube is elliptical or flattened in cross section and bent into circular form. One end is soldered to a central block through which the fluid enters, and the other end is sealed and coupled by a link to a pivoted quadrant with teeth meshing with those of a pinion on the pointer spindle. Backlash between the teeth is absorbed by a hairspring exerting constant force on the pinion. An increase of pressure within the tube tends to change its cross section from elliptical to circular, and the tube consequently uncoils slightly, thus turning the pointer.

If the case enclosing the gauge is made airtight and the air is exhausted from within the case, the gauge measures absolute pressure (psia or pounds per square inch absolute); if the pressure inlet of such a gauge is then opened to the atmosphere the gauge would read atmospheric pressure, approximately 14.7 psia. If the airtight case is provided with a pressure inlet the gauge may be used to measure differential pressures existing between two sources of pressure connected to the two pressure inlets. Usually the case of the gauge is not airtight and the external surface of the Bourdon tube is thus subjected to ambient atmospheric pressure. Such a gauge measures "gage" pressure (psig or pounds per square inch gage), i.e., the value of the inlet pressure above atmospheric pressure. This instrument may be used as a vacuum gauge, measuring pressure, below atmospheric pressure; the reduction in pressure causes the Bourdon tube to coil further, and the mechanism must be arranged in reverse fashion to cause the pointer to move clockwise with increasing vacuum. A compound gauge reads for both pressure and vacuum, the dial markings for vacuum being placed to the left of the zero of the pressure scale.

Diaphragm Capsule.—One direct-reading gauge utilizes as the elastic pressure-sensitive element a hollow sealed disk-shaped capsule made from two corrugated metal diaphragms. Changes in pressure cause motion of the centre of the capsule, and this motion is amplified by a mechanical linkage to control movement of the pointer over a calibrated dial. When proper precautions are taken in design to reduce hysteresis, temperature effects and

the like, sustained accuracies on the order of two or three parts in 1,000, or better, are obtainable.

For measurement of absolute pressure, as in the aneroid barometer, the capsule is evacuated, and the varying atmospheric pressure acts on the exterior surface of the capsule. A spring is arranged to supplement the elastic resistance of the capsule to the force of atmospheric pressure, and the motion of the centre of the capsule is transmitted to the indicating pointer by appropriate linkage.

Bellows.—A metal bellows may be used in a pressure gauge designed for pressure ranges of from a few inches of water (i.e., the pressure produced by a column of water a few inches high) to 10 or 15 lb. per square inch. The large deflection of the bellows for small pressure changes provides the high sensitivity needed in gauges for such low-pressure ranges.

Materials.—Bourdon tubes are commonly of phosphor-bronze, beryllium-copper or Monel metal (a nickel-copper alloy), for pressures up to a few hundred pounds per square inch; above this pressure or for elevated temperatures, the tubes are made of steel to obtain a greater elastic range and a smaller change of elasticity with temperature. Diaphragms are most frequently made of phosphor-bronze, beryllium-copper or Ni-Span (a nickel-iron-chromium-titanium alloy). Bellows are usually of brass although bellows of stainless steel and beryllium copper are also available.

Reading Instruments.—All of these gauges are also available in designs to provide a continuous record of pressure. A circular-chart gauge, comprising a Bourdon element of several complete turns, has a pen arranged to trace a record on a circular chart driven by clock work. A microbarograph records absolute atmospheric pressure on a paper strip wound around a drum driven by clockwork. The necessary high sensitivity is obtained by use of an evacuated bellows element whose motion is magnified by the pen linkage. The pressure range of the instrument is generally 28.5 to 31 in. of mercury (about 14 psia to 15.2 psia), for which range the recording pen moves about 6 in.

Remote Indicators.—For remote indication of pressure, or for control purposes, the pressure is often converted into an analogue quantity. This quantity is commonly a direct current voltage or an air pressure. Direct current voltage is used frequently in telemetering systems, and air pressure in industrial recording and control equipment.

One such instrument, designed for use in measuring the pressure at points remote from a pressure recorder, has the elastic motion of a hollow metal cylinder exposed to the pressure arranged to vary the electrical resistance of strain gauges attached to the surface of the cylinder. The strain gauges are connected in a bridge circuit in such a way that the bridge output voltage varies in a linear fashion over the range from zero to perhaps 50 millivolts as the cylinder pressure varies from zero to the rated pressure of the instrument, the rated pressure being from a few hundred psig to 50,000 psig. The output voltage, proportional to the pressure, may be recorded or displayed by use of appropriate electrical instruments. For rapidly changing pressures, to which this instrument will respond, the output voltage is usually recorded by use of an oscillograph.

A common system is that in which the pressure to be measured is converted by use of a force-balance mechanism into an analogue pneumatic pressure in the range 3 to 15 psig. The instrument may be adjusted to have an input pressure range from a small fraction of the analogue pressure range to several times the analogue pressure range. The analogue pressure may be transmitted to a remote location and connected to an indicator, recorder, or used for control purposes. The pressure-sensitive element of the pressure transmitter is a diaphragm acting against a coil spring. Slight motion of the diaphragm due to change in pressure causes a relatively large change in the pneumatic pressure in the force-balance bellows assisting the spring, and the analogue pressure is the pressure in the bellows necessary to maintain the diaphragm near its mid-position. The permitted motion of the force-balance bellows and of the diaphragm and main spring is extremely small, and the system is characterized by high sensitivity and low hysteresis.

Other methods for converting the motion of a mechanical pres-

sure element to an analogue voltage include the use of variable resistors (potentiometers), differential transformers, variable capacitances and variable inductance or variable reluctance devices. In another method the motion of a diaphragm varies the tension, and thus the frequency, of a vibrating wire maintained in motion by a magnetic field acting on an alternating current passing through the wire. The pressure is then represented by an electrical frequency equal to the wire frequency.

Primary Pressure Gauges.—All instruments of the types described above require calibration against known pressures. The two principal instruments used for such calibration are liquid column instruments such as the manometer and barometer (*q.v.*) and dead-weight piston gauges.

A dead-weight piston gauge comprises a vertical cylinder, the

upper end of which is closed by a weight-loaded piston. The cylinder is filled with oil, and a pressure connection is provided at the lower end to which an instrument under test may be connected. A pump, operated by a handwheel, is provided to adjust the volume and pressure of the system so that the weight-loaded piston assumes a floating position in the cylinder. The pressure developed by a dead-weight piston gauge is nominally equal to the weight of the piston and its load divided by the cross-sectional area of the piston.

Such instruments are capable of high precision, on the order of one part in 10,000, or better; when precision greater than about one part in 200 is desired corrections must be made including corrections for a number of environmental variables. The following are the most important corrections that must be considered: change in effective piston area due to temperature changes, amounting to 10 to 20 parts per million per degree Centigrade; difference in value of local gravity from standard value of 980.665 cm./sec./sec., amounting to more than one part in 1,000 in some localities; variation in effective area of piston due to elastic distortion of piston and cylinder under pressure, amounting to perhaps 100 parts per million per 1,000 psi in some designs; the buoyancy of the liquid on submerged protuberances of the piston, applicable only for pistons of nonuniform cross-sectional area; the hydrostatic head of liquid between the bottom of the piston and the point of pressure measurement; and the buoyancy of air on the weights, frequently amounting to about one part in 7,000.

For high accuracy at high pressures the controlled clearance piston gauge has been developed, in which a variable hydrostatic pressure is applied to the exterior surface of the cylinder to reduce errors due to elastic distortion.

For pressures below about 50 psig piston gauges are available in which the working fluid is air, and the piston and cylinder operate as an air bearing.

PRESTEIGNE, an urban district and the county town of Radnorshire in the Brecon and Radnor parliamentary division of

Radnorshire, Wales, 26 mi. (42 km.) NW of Hereford by road and on the Lugg, which there forms the boundary between Wales and England. Pop. (1961) 1,190. The village, lying on the English side of Offa's dyke, was in the lordship of Moelynaidd until the 14th century, when Bishop David Martin of St. David's (1296-1328) conferred market privileges upon his native place. There is an annual May fair.

In 1542 Presteigne was named as the meeting place of the county sessions for Radnorshire in conjunction with New Radnor; a winter and summer assize court is held. It has the fine parish church of St. Andrew, dating chiefly from the 15th century but with traces of Norman work; curfew is rung from it at eight o'clock every evening.

Presteigne is the most easterly spot on the Welsh border; hence the expression "from St. David's to Presteigne." The main industries are agriculture and forestry.

PRESTER JOHN (PRESBYTER JOHN; *i.e.*, John the Elder or John the Priest), a legendary medieval character, allegedly the king-priest of the Indies, a mighty Christian potentate in the East, of fabulous wealth and power.

The Legend.—Following the report made to the papal court in 1145 (see *The Historical Background*, below) a 13th-century chronicler, Alberic de Trois Fontaines, recorded that in the year 1165 a letter was sent by Presbyter John, the king of the Indies, to several European rulers, including Manuel I Comnenus, the Byzantine emperor, and Frederick I Barbarossa, the Holy Roman emperor. This letter, in Latin, is available in numerous copies. At an early date it was translated into other languages, including Hebrew and Old Slavonic. The letter was addressed primarily to Manuel I Comnenus. It is curious that no Greek text of the letter has ever been heard of and no reference to it can be found in Byzantine sources. It is safe to assume that it was actually composed in Latin by a Westerner who was well acquainted with the Byzantine Empire and versed in Eastern legendary literature. This would account for occasional Greek words and Greek turns of phrase in the text.

The letter is an obvious literary fiction. It was circulated mainly in the West and contains several drastic interpolations which prove the great popularity of the document. That it has a strong anti-Byzantine bias is evident from the title: Manuel is addressed as "governor of the Romans." This betrays a Western hand, for people in the West were reluctant to concede any higher title to the Byzantine rulers. On the other hand, John describes himself as "lord of lords," *dominus dominantium*, a highly ambitious title, with an implicit claim to divine authority. He writes to Manuel as to an inferior and invites him to come to his realm in person. There is subtle irony in the question, "does Manuel hold the true faith?" John had heard that "thy little Greeks" (*graeculi*) considered Manuel as divine. For his part, John knew well that he himself was but a mortal.

The land of John, "the three Indies," was indeed a miraculous land: "honey flows in our land, and milk abounds everywhere." Not only did the land abound in natural riches, and in all sorts of fabulous marvels, it was also a land of peace and justice, no vice whatever was known there, no flattery or envy, no avarice, no strife; there were no liars in the land, no robbers or thieves, and also no poor. The splendour of the royal palace was described in glamorous superlatives. Yet, in spite of all this might and glamour, John had, in humility, chosen for himself an inferior rank, that of priest, *presbyteratus nomine*. Too many glorious titles were used at his court: his butler was an archbishop and a king, and even his chief cook was a king and a prior. Accordingly it was not fit for his highness to use any such honorific name for himself. He declared his intention, nevertheless, to come to the Holy Sepulchre with a great army, to fight the enemies of the cross.

The land of John can be identified: his royal throne and palace were at Susa, in Persia. The patriarch of St. Thomas, the bishop of Samarkand, and the protopope of Susa attended his court.

Altogether the letter of Prester John is a curious document, but it had a serious purpose. Prester John posed as an ideal prince. His realm was a kind of earthly paradise, but he wanted to give

a lesson in modesty to Western rulers and to rebuke them for their vainglory. The letter belongs to the peculiar branch of medieval lore of which the Alexander Romance (*q.v.*) is the best-known specimen. It has direct links with the legend of St. Thomas the Apostle and his shrine and with the story of the Three Magi. It may also be compared with other Oriental tales, *e.g.*, with the Arabian story of Sinbad the Sailor in the *Thousand and One Nights* and with the travels of Eldad ha-Dani (*q.v.*), "the Arabian Nights of the Jews." The name "Presbyter John" itself belongs to an ancient apocryphal tradition. He is an enigmatic person to whom the writings of St. John the Apostle were often attributed. Indeed the name occurs also in the canonical epistles of St. John. It seems that the name itself was the pivot of the whole legend and was not derived from any historic personality.

The descriptive part of the letter—the fabulous picture of India—belongs to the cycle of St. Thomas. On the other hand, the letter also reflects the historical setting in which it was written, *i.e.*, the period of the early Crusades. The image of a powerful Christian monarch, somewhere in the mysterious East, ready to support the Christian cause against the infidel, could not fail to impress the minds of all those who were involved in the crusading enterprise. The land of Prester John was accordingly included in medieval maps, and attempts were made to reach this land of marvels and to establish contact with its glorious ruler. "India" was a vague and comprehensive term in medieval geographical lore, almost coextensive with the East.

The Historical Background.—In 1145 Bishop Hugh of Gebal in Syria (modern Jebeil, Lebanon) came to the papal court at Viterbo and brought a tale concerning Prester John. His story, carefully recorded by Otto of Freising in his chronicle, was that some few years before a certain John, "priest and king," dwelling in the area "beyond Persia and Armenia," a Christian but a Nestorian, defeated in a bloody battle the Samiardi, the kings of the Persians and the Medes, and stormed Ecbatana, their capital. He intended to proceed to Jerusalem, to help the church there, but was unable to cross the Tigris. It was said of him that he was a lineal descendant of the Magi and possessed enormous wealth. The story seems to refer to the victory of Yeh-lü Ta-shih, the founder of the Khara-Khitai Empire in central Asia, over the Seljuk Sultan Sanjar, at Qatwan, near Samarkand, in 1141. It is strange, however, that the Mongol conqueror was mistaken for a Christian king. Obviously, there was a queer admixture of legend in Hugh's story. The mention of the Magi is highly characteristic. Bishop Hugh, an expert diplomat, was but reporting what he had heard in Syria. Yet, there could have been a grain of truth even in these distorted rumours. Nestorian Christians did play some role in the Mongolian realm. The story of Hugh was believed at the papal court.

In 1165 the letter of Prester John arrived. A few years later, in 1177, the pope, Alexander III, dispatched a letter to John, "the illustrious and magnificent king of the Indies and a beloved son in Christ." The pope quoted the information he had received of the king's piety and Christian devotion, both through common report, and especially from his confidant and physician, Philip, who had been in touch with some honourable persons of John's kingdom. It was reported to the pope that John wanted reconciliation with the apostolic see and desired to have a church of his own in Rome and an altar in Jerusalem. The pope was willing to grant these requests if John would specify his wishes and send his envoys with a sealed letter. The pope does not call John "Presbyter" in this letter, but it seems obvious that he was referring to the famous letter of 1165. The letter of the pope was written two months after his reconciliation with Frederick Barbarossa, after years of bitter struggle, while his position was still insecure. He was much interested in the possibility of obtaining allies from the remote East. Nothing is known of the fate of the pope's letter.

In 1221 information came to Rome from two prominent Western churchmen—Jacques de Vitry, bishop of Acre, in Palestine, and Cardinal Pelagius, who was engaged at that time with the crusading army at Damietta—concerning a recent victory of a certain King David of India over the Muslims. David was sup-

posed to be a son or a grandson of Prester John. (Jacques de Vitry says simply: "commonly called Prester John.") Strange as it may seem, the person in question was probably no other than Genghis Khan. It should not be forgotten, however, that these were rumours and there was a great deal of wishful thinking in them. On the one hand, the strength of the Nestorian Church in central Asia and Persia could easily have been exaggerated. On the other hand, certain Mongol rulers at that time were interested in an alliance with the West against the common enemy, the Muslim, in Syria and the Holy Land, and their interests to some extent coincided with those of the crusaders. In the 13th and early 14th centuries direct contact between the West and the Mongols was established by missionaries and by lay travelers, such as Joannes de Plano Carpin, Andrew of Lonjumel, William of Rubruquis, Marco Polo, Giovanni di Monte Corvino (*qq.v.*) and Oderic of Pordenone. All these were looking for Prester John, and all identified him differently.

A well-known Syriac writer of those times, Bar-Hebraeus (*q.v.*), told in his history of a Christian tribe, the Keraits, which was ruled over by an Ung Khan (Wang Khan) "who is called King John" (Malik Yuhanna). An Ung Khan was known to Rubruquis and to Marco Polo. A modern theory that "Ung Khan" should be identified as Prester John is, however, hardly tenable and can be discarded on chronological grounds.

After the mid-14th century the search for Prester John was directed toward Ethiopia. This was first suggested by Jordan de Sévérac, a Dominican friar who went to India and failed to find Prester John there. He had no first-hand knowledge of Ethiopia and his description of that country was mainly imaginary. Very soon, however, the identification of Prester John with the negus of Ethiopia was generally accepted. It was popularized by Jesuit missionaries to that country and by Portuguese navigators. Some modern scholars contend that the image of Prester John was originally based on that of the Ethiopian ruler and that the name John is a rendering of *Zan*, the royal title in Ethiopic. This contention cannot be upheld. The title *Zan* was probably not in use before the 16th century. Moreover, the legend and other stories definitely locate Prester John in Asia and in the Nestorian area. Even so, some memories of a Christian king in Ethiopia might be included in the legendary image of Prester John.

PRESTON, THOMAS (1860–1900), Irish physicist, who made original contributions on heat, magnetism and spectroscopy, and carried out experiments on the influence of magnetic fields on spectral lines, was born in Kilmore, County Armagh, Ire., on May 23, 1860. He studied in Dublin and became professor of natural philosophy in University College, Dublin, in 1891. He was elected a fellow of the Royal Society of London in 1898. The same year Preston discovered an empirical rule concerning types and structures of Zeeman patterns (see **ZEEMAN EFFECT**). Preston died in Dublin on March 7, 1900. (D. McK.)

PRESTON, a municipal, county and parliamentary borough and port of Lancashire, Eng., 21 mi. (34 km.) S.S.E. of Lancaster. Pop. (1961) 113,341. It is built on a ridge rising above the Ribble where that river is crossed (about 15 mi. [24 km.] above its mouth) by the west coast road and railway to Scotland. It is the administrative centre of the county of Lancashire.

From early days its geographical position made it a trade centre

with an agricultural market. Its importance progressively increased after the advent of the cotton industry, to which have been added a wide range of manufactures including engineering, aircraft and vehicles, chemicals and soap, boilers and ships, paper, electrical appliances, textiles and optical goods.

Preston became an independent port in 1843, the corporation acquiring the docks in 1883. The main wet dock is 3,240 ft. (988 m.) long and 600 ft. (183 m.) wide. There is a total quayage of 8,500 ft. (2,591 m.) and the depth of the channel at ordinary spring tides is 22–25 ft. (67–76 m.).

Preston is the chief mart for the produce of the great Fylde agricultural district, with two large covered markets: for general produce (wholesale and retail); and for fish. There are also corn, butter and egg markets and a wholesale fish market at the railway station. The important cattle market holds thrice-weekly sales throughout the year. There are horse sales each month.

The numerous parish churches include that of St. John (1855) which occupies a site that has carried a church from early times. Among several Roman Catholic churches is that of St. Walburge (1854). The town hall was almost destroyed by fire in 1947. The Harris art gallery, library and museum were established by the trustees of E. R. Harris in 1879, and a new building was opened in 1893. This contains William Shepherd's library, the Francis Thompson collection and the Spencer collection of children's books, the Newsham collection of pictures and collections of pottery, glass, costumes, etc. The grammar school, dating from 1550 (Preston had a schoolmaster as early as 1339) is housed in a modern building in Moor park. The parliamentary borough returns two members. The county borough was created in 1889.

History.—Preston, otherwise Prestune, was near the Roman station at Walton-le-Dale, and the great Roman road running from Warrington passed through it. It is mentioned in Domesday Book as one of Earl Tostig's possessions which had fallen to Roger de Poitou, and on his defection it was forfeited to the crown. Henry II (about 1179) granted the burgesses a charter—the first of 14 royal charters granted to Preston (there is evidence of an even earlier charter of 1100–01). Elizabeth I (1566) granted the town its great charter which ratified and extended all previous grants. Charles II (1662 and 1685) granted charters, by which an additional weekly market on Wednesday was conceded and a three-day fair, beginning on March 16. The most important industry used to be woolen weaving. Other early industries were glovemaking and linen weaving. The first cotton-spinning mill was built in 1777 in Moor lane, and in 1791 John Horrocks built the Yellow factory. In 1835 there were 40 factories, chiefly spinning, yielding 70,000 lb. of cotton yarn weekly.

A guild existed perhaps in Saxon times, but the grant of a guild merchant dates from Henry II's charter, about 1179. The first guild of which there was any record was celebrated in 1328, at which time it was decided to hold a guild every 20 years. Up to 1542 they do not appear to have been regularly celebrated, but after that year they were held at regular intervals of 20 years except that the 1942 guild was postponed because of World War II. The mayor elected for the year in which the guild is held is known as the guild mayor. The first mention of a procession at the guild is in 1500. One of the most important items of business was the enrolling of freemen, and the guild rolls are records of the population. The statement that Preston was burned in 1323 by the Scots is probably false. The town suffered severely from the Black Death (1349–50), and again from pestilence in the year Nov. 1630 to Nov. 1631. During the Civil War Preston became the Lancashire royalist headquarters. In Feb. 1643 a parliamentary force marched from Manchester and successfully assaulted it, but in March the earl of Derby recaptured the town. The royalists did not garrison it, but after demolishing the greater part of the works left it unfortified. After the battle of Marston Moor Prince Rupert marched through Preston in Sept. 1644 and carried the mayor and bailiffs prisoners to Skipton castle. On Aug. 17, 1648, the royalist forces under the duke of Hamilton and Gen. Marmaduke Langdale were defeated at Preston by Cromwell. During the rebellion of 1715 the rebel forces entered Preston Nov. 9, and after proclaiming the chevalier de St. George king, remained there

for several days, during which the government forces advanced. The town was assaulted, and Gen. Thomas Forster surrendered his army to the king's forces. In 1745 Prince Charles Edward marched through on the way south and north. The borough returned two members from 1295 to 1331, then ceased to exercise the privilege till 1529, but after that date (except in 1653) it always sent two representatives to parliament. In the 18th century Preston had a high reputation as a centre of fashionable society, and earned the epithet still familiarly associated with it, "proud." Sir Richard Arkwright (1732–92) was born there.

See H. Fishwick, *History of the Parish of Preston* (1900); W. P. Fitzgerald, "The Ribble Basin," *Journ., Manchester Geog. Soc.* (1927).

PRESTONPANS, a small burgh and seaside resort of East Lothian, Scot., on the Firth of Forth, 9 mi. (14 km.) E of Edinburgh by road. Pop. (1961) 3,105. The name refers to the pans or ponds, in which the monks of Newbattle Abbey (a 12th-century Cistercian foundation now a college for adult education) made salt by evaporation. The chief occupation is coal mining, and there are manufactures of firebricks, tiles, pottery, and soap, besides brewing.

A mile to the east of the village is the site of the Battle of 1745, in which Prince Charles Edward and his Highlanders gained a complete victory over the royal forces under Sir John Cope. Seton Castle, about 1½ mi. NE, was built in 1790 by Robert Adam on the site of Seton Palace to which Mary, queen of Scots, and Lord Darnley rode after David Rizzio's murder in 1566; she visited the castle again, with the earl of Bothwell (James Hepburn) in 1567 just after Darnley's murder. In the castle grounds is the incomplete 15th-century collegiate church of Seton.

PRESTWICH, a municipal borough in the Middleton and Prestwich parliamentary division, Lancashire, Eng., 4 mi. (6 km.) NW of Manchester by road. Pop. (1961) 34,209. It has cotton and rayon mills but is mainly residential. It is contiguous with the cities of Manchester and Salford. It was incorporated in 1939. There are traces of the Roman occupation but the place name is of Anglo-Saxon origin. The present parish church dates from the 15th century.

PRESTWICK, a police burgh of Ayrshire, Scot., on the eastern shore of the Firth of Clyde, 3 mi. (5 km.) N of Ayr and 30 mi. (48 km.) SW of Glasgow by road. Pop. (1961) 12,562. It is a seaside and golfing resort with a broad sandy bathing beach two miles long and a large swimming pool. Besides the Prestwick championship golf links there are two other good courses. The international airport is the most important in Scotland, its development being the result of good climatic conditions. There is a 15th-century Mercat cross (rebuilt 1777), and the ruined church of St. Nicholas is a landmark for shipping. Bruce's Well in Kingesshoe estate is said to mark the place where Robert I, "the Bruce," was cured of a skin disease. Local industries are coal mining, aircraft construction, and light engineering. Prestwick is thought to have been a burgh since 983 and was granted a royal charter by James VI in 1600. It became a police burgh in 1903.

PRETORIA, capital city of Transvaal Province and administrative capital of the Republic of S.Af. Pop. (1960) 298,633, including 154,789 Whites, 131,824 Bantu, 7,167 Asians, and 4,852 Coloureds. It lies in a valley between the eastern foothills of the Magaliesberg through which flows the Apies River. The original town was laid out in rectangular blocks around Church Square which is surrounded by some of the city's most important buildings, including the Raadsaal (old government buildings), former meeting place of the republican *volksraad* (Parliament) and now occupied by the provincial council; the Palace of Justice, the General Post Office; and the headquarters of the South African Reserve Bank. At the centre of the square is the statue of Paul Kruger; his house, now a national monument, is nearby on Church Street.

Running east-west and north-south from the square are the city's principal streets: Church Street, one of the world's longest straight streets (11.58 mi. [18.64 km.]) and Paul Kruger Street. These and other streets in the central area are flanked by imposing new skyscrapers, erected during the boom period following World War II. The Union buildings, containing most of the cabinet

VOORTREKKER MONUMENT

offices, stand on the slopes of Meintjes' Kop. Erected during 1910-13, they overlook terraced gardens in which is the statue of Gen. Louis Botha, the union's first prime minister.

Pretoria has Anglican and Roman Catholic cathedrals and about 70 Afrikaans and numerous other churches serving various denominations. There are many public and private schools, a technical college, and a teachers' training college. The University of Pretoria was founded in 1930 from the Transvaal University College (1908). It includes the only faculty of veterinary science in South Africa. The headquarters of the University of South Africa are also in Pretoria. The Transvaal Museum is in Paul Kruger Street, and the National Historical Cultural Museum adjoins the National Zoological Gardens. South of the city is the Voortrekker Monument, inaugurated on Dec. 16, 1949, as a tribute to the *voortrekkers* (pioneers), which has a museum.

The city is linked by rail and road with the Witwatersrand and with the rest of the republic and neighbouring countries. Air traffic uses the nearby Jan Smuts International Airport. The South African Iron and Steel Industry (I.S.C.O.R.) was established in 1928; since then, the production of iron and steel and subsidiary undertakings have been the city's most important industries.

Pretoria was founded in 1855 and named after the famous *voortrekker* leader Andries Pretorius. It became capital of the South African Republic (Transvaal) in 1860. During the South African War, after Winston Churchill had been held a prisoner of war there for a short while, it was declared an open town and occupied by British troops on June 5, 1900. The Peace of Vereeniging was signed at Melrose House on May 31, 1902. On the establishment of the Union of South Africa in 1910, Pretoria became its administrative capital. See also references under "Pretoria" in the Index.

(H. P. H. B.)

PRETORIUS, the surname of two Boer leaders in the republics established in South Africa during the Great Trek.

ANDRIES WILHELMUS JACOBUS PRETORIUS (1798-1853), commandant general in Natal and subsequently in the Transvaal, achieved fame by leading the Boers to victory over Dingaan's Zulus at the Battle of Blood River on Dec. 16, 1838, and was thereafter until his death the most prominent figure in Boer politics. Born near Graaff-Reinet, Cape Colony, on Nov. 27, 1798, Pretorius left the colony in September 1838 and trekked to Natal, which he had visited previously. He had served as a commandant in the Cape Colony and on his arrival the Natal *volksraad* (elected council) appointed him commandant general (November 1838). Pretorius raised a commando and prepared to move against the Zulus under Dingaan, whose attacks had been endangering the security of the trekkers since the massacre of Piet Retief and his party (February 1838). At Blood River the encamped commando of

nearly 500 Boers withstood the onslaughts of about 10,000 Zulu warriors without loss, while the Zulu dead numbered more than 3,000. When Panda (Mpande) announced his revolt against his brother Dingaan (October 1839), Pretorius decided to assist him and exact from Dingaan reparations outstanding under the peace agreement concluded in May. The combined forces were successful at the Battle of Magongo (January 1840) and in February Pretorius, after receiving a huge number of cattle, returned to Natal in triumph leading his "cattle commando," having established Panda as "ruling Zulu prince."

Inheriting the policy of his more able predecessor, Retief, of uniting the trekker communities in a single republic, Pretorius concluded an agreement with head commandant Andries Potgieter in October 1840, which brought the Potchefstroom and Winburg settlements (see *TRANSVAAL: History: The Trekker State*) into a federal union with Natal. Pretorius quarreled frequently with the Natal *volksraad*, which hedged his office with restrictions and even sought to abolish it in peacetime. The *volksraad's* interference explains his failure to prevent a small British force from occupying Durban in May 1842, but Pretorius lost an opportunity of forcing its surrender before commencing a siege. On the arrival of British reinforcements, Pretorius withdrew to Pietermaritzburg and resigned his post of commandant general.

Pretorius accepted the ensuing British annexation of Natal (see *NATAL: History*) as a *fait accompli* and even took the oath of allegiance to Queen Victoria. Having unsuccessfully urged local British officials to redress the grievances of the Natal Boers, especially those arising from native settlement in locations among the Boer farms, he sought, in October 1847, to interview the Cape governor, Sir Henry Pottinger, who was then in Grahamstown, Cape Colony, on their behalf. Sir Henry refused to see him and Pretorius, after expressing his views in the frontier press, returned to Natal determined to organize a further trek.

The proclamation by Sir Harry Smith, Pottinger's successor, of the Orange River Sovereignty (February 1848), brought British rule up to the Vaal River. Pretorius, believing this to contravene a verbal undertaking given him by Sir Harry, toured the high veld addressing protest meetings before establishing himself in the Magaliesberg, north of the Vaal. In July 1848 he accepted an invitation from the Boers of Winburg in the sovereignty to lead an armed protest against the proclamation. After occupying Bloemfontein, he was defeated by Sir Harry Smith at Boomplaats (August 1848), and withdrew to the Transvaal, outlawed and with a price on his head of £2,000.

Supported by many of his followers from Natal, Pretorius, one of four Transvaal commandants general, became the leader of the Boers of Potchefstroom and Rustenburg, with Potgieter of the Zoutpansberg as his chief rival. Pretorius received appeals from Boer malcontents in the sovereignty and from the Basuto chief Moshesh to help them expel the British (1850-51). Playing upon British fears that he might intervene, Pretorius undertook to support an investigation by two British commissioners into the affairs of the sovereignty, provided that they formally recognized the independence of the Transvaal Boers. As a result, his sentence of outlawry was withdrawn (December 1851) and he met the commissioners near the Sand River, where a convention in this sense was signed (Jan. 17, 1852). After returning to Rustenburg, he crowned his success by persuading Potgieter, who had opposed these negotiations, to approve the convention (March 1852). With the Transvaal independent and more or less united, Pretorius hoped that the British government would now recognize the independence of the sovereignty Boers. This recognition came in the Bloemfontein Convention of Feb. 23, 1854, seven months after his death in the Magaliesberg (July 23, 1853). In 1855 the district and town of Pretoria were established and named in his honour.

MARTINUS WESSEL PRETORIUS (1819-1901), eldest son of Andries Wilhelmus Jacobus Pretorius, best known for his unsuccessful efforts to unite the South African Republic and the Orange Free State, is the only man to have been president of both states. Born near Graaff-Reinet, Cape Colony, on Sept. 17, 1819, he succeeded his father as commandant general of Potchefstroom and Rustenburg (1853) and in 1854 led a successful commando

against Makapan, a recalcitrant chief in the northern Transvaal.

Pretorius tried to continue his father's policy of uniting the trekker Boers, seeking to establish a unitary state in the Transvaal which could then be united with the newly independent Orange Free State. Less able and diplomatic than his father, he unwisely pursued these aims simultaneously, using high-handed and unconstitutional methods, allowing his personal ambitions considerable rein and provoking much opposition. In December 1856 a *grondwet* (constitution) for the South African Republic, which had been drafted on his initiative in 1855, was confirmed by the Potchefstroom and Rustenburg Boers, who then elected Pretorius as president (January 1857). The Zoutpansberg Boers repudiated these proceedings, while Lydenburg declared its independence.

Ignoring these difficulties, Pretorius turned to the Free State. In April 1857 he arrived in Bloemfontein and, with a few friends, attempted a *coup d'état*. Ignoring the Free State constitution, he claimed the territory in his father's name and invited his Winburg supporters to rebel. After being forced to withdraw by the president of the Free State, J. N. Boshoff, he returned again with a commando, but the calming influence of Paul Kruger, commandant of Rustenburg, prevented a clash and the two presidents recognized each other's independence (June 1857). Pretorius persevered, however, in his scheme to unite the republics and was elected president of the Free State in December 1859.

In the Transvaal the Zoutpansberg and Lydenburg-Utrecht Boers had meanwhile joined the South African Republic and in April 1860 a united *volksraad* ratified the *grondwet* which had been accepted by the Zoutpansberg in 1858. The *volksraad* then charged Pretorius with violating the constitution by accepting office in the Free State and on his arrival from Bloemfontein offered him an honourable discharge (September 1860). Refusing to resign, Pretorius returned to Bloemfontein and the Transvaal plunged into anarchy. Fighting ensued in 1862 between factions supporting the rival claimants, Stephanus Schoeman and W. J. van Rensburg, to the post of acting president. In April 1863 Pretorius resigned the Free State presidency, thus abandoning all hope of uniting the republics, and returned to the Transvaal where, after further fighting, unity was established by his reelection as president. He resumed office in May 1864.

After 1864 Pretorius tried to improve the quality of the Transvaal administration and introduced regular budgets in an unsuccessful attempt to resolve the state's financial difficulties. He issued a proclamation in April 1868, extending the republic's boundaries as far as Lake Ngami, Bechuanaland, in the west and Delagoa Bay in the east, while the Tati goldfield north of the Limpopo River was also included. Portuguese and British protests forced Pretorius to withdraw most of his claims in 1869, in which year he was reelected president; but he maintained a claim to the diamond fields of the lower Vaal. After failing to persuade the African tribes there to place themselves under the republic, Pretorius alienated the diggers by granting a diamond monopoly to three of his friends (June 1870). In 1871, without consulting the *volksraad*, he agreed to refer the boundary question to the arbitration of R. W. Keate, lieutenant governor of Natal. The Keate award went against Boer claims, for which the *volksraad* blamed Pretorius, and he was forced to resign (November 1871).

After the first British annexation of the Transvaal (April 1877), Pretorius acted as chairman of a committee of Boer leaders who pressed in 1879 for the restoration of their independence. Sir Garnet Wolseley, high commissioner for southeast Africa, ordered his arrest on a charge of treason in January 1880, but later released him and offered him a seat on his executive council, which Pretorius declined. When the Boers took up arms in December 1880, and proclaimed the republic, they appointed Kruger, Pretorius, and Piet J. Joubert to govern as a triumvirate. Pretorius was a signatory to the Pretoria Convention (August 1881), but in May 1883, when the triumvirate gave way to the presidency of Kruger, he retired from public life. He died at Potchefstroom on May 19, 1901.

For Andries Pretorius, see G. S. Preller, *Andries Pretorius*, 2nd ed. (1940). For both Pretoriuses see E. A. Walker, *A History of Southern Africa*, 3rd ed. (1957). (N. G. GA.)

PREVENTIVE MEDICINE. Historically, the prevention of disease is the ideal of medicine. It has two aspects: the preventive medicine of the community—an important part of what is broadly termed public health (*q.v.*); and the prevention of disease or its aftereffects in the individual.

Hippocrates (fl. 400 B.C.) classified causes of disease into those concerned with seasons, climates, and external conditions, and those more personal causes such as irregular food, exercise, and habits of the individual. Through the Middle Ages the principles of preventive medicine were ignored, in spite of the scourges of leprosy and plague. With the Renaissance came the new learning which revolutionized the whole content of medicine. Practitioners began to observe the relation of the seasons, environmental conditions, and personal contact to the incidence of disease.

Concurrent with the growth of medical knowledge there was an empirical movement of practical prevention. For example in 1388 there was passed the first sanitary act in England, directed to the removal of nuisances; in 1443 came the first plague order recommending quarantine and cleansing; and in 1518 the first rough attempts at notification of epidemic disease and isolation of the patient were made. John Graunt initiated the study of mortality statistics in England in the 17th century. Thomas Sydenham (1624–89) laid the basis of epidemiology by his observation of cases, deduction of laws of prevalence, and hypothesis of "epidemic constitutions." Bernardino Ramazzini, in Italy, published a treatise on occupational disorders in 1700. Richard Mead, an English practitioner in the first half of the 18th century, wrote on poisons, on plague and methods of its prevention, and on smallpox, measles, and scurvy. Edward Jenner introduced vaccination (1798). The early and middle years of the 19th century were notable for discoveries in the transmission of contagious diseases such as typhus (John Howard), cholera (John Snow), typhoid fever (William Budd), and childbed (puerperal) fever (Oliver Wendell Holmes and Ignaz Semmelweis). In the same period increasing attention was given to problems of hygiene and nutrition.

The modern era in preventive medicine opened in the late 19th century with Louis Pasteur's discovery of the role of living microbes as the cause of infections. In 1893 Theobald Smith established the principle of insect-borne transmission of disease. Serological tests were developed, such as the Widal reaction for typhoid fever (1896) and the Wassermann test for syphilis (1900). An understanding of the principles of immunity led to the development of active immunization to specific diseases. Parallel advances in treatment opened other doors for prevention—diphtheria by antitoxin (Emil von Behring) and in syphilis by Salvarsan (Paul Ehrlich). In 1932 the sulfonamide drugs and later the antibiotics including penicillin, streptomycin, chlorotetracycline (Aureomycin) and chloramphenicol (Chloromycetin) afforded new opportunities of prevention and cure.

After 1900 there were many advances in preventive medicine other than those related to infectious diseases. The use of X rays and radioactive substances in the diagnosis and treatment of disease (*e.g.*, tuberculosis and cancer) as well as in fundamental physiological research opened new possibilities. A greater understanding of endocrine functions, with the production of prepared extracts such as insulin (Sir Frederick Banting and Charles Best, 1921), thyroid, pituitary extract, and hormones, led to preventive measures in certain metabolic diseases. The role of nutrition in health and disease and the isolation of many essential food factors illustrated the importance to health of adequate diet. Other 20th-century advances in preventive medicine included a wider recognition of psychological factors in relation to total health, new surgical techniques, new methods of anesthesia, genetics research, and the application of statistical methods to medical problems.

PREVEZA, a town and *nomos* (department) of western Greece. The town is a small seaport at the entrance to the Gulf.

of Arta, 66 mi. (106 km.) S of Ioannina (Yannina, Janina) by road. Pop. (1961) 11,172. The department, which formerly included the islands of Leukas and Meganisi, is now restricted to the mainland; it has an extent of 423 sq.mi. (1,096 sq.km.) and a population (1961) of 62,523. Though well sheltered, the town is difficult to approach from the open sea, the only entry being through the 21-ft. (6 m.)-deep Khrisanthis Channel. Unloading in the harbour, which has an area of 17 ac. (7 ha.), is usually performed by lighters. There is no railway, but there are road links with Arta and Ioannina. Olives thrive in its vicinity, and these, together with butter, cheese, hides, and wool, account for most of its exports. Founded by Pyrrhus, king of Epirus, about 290 B.C., the place was in later times held and fortified successively by Venetians, French, and Turks. Preveza was seized by Ali (q.v.; the Lion of Janina) in 1798 and recovered by Greece in 1912 during the First Balkan War (the transfer being confirmed by peace treaty in 1913).

(Wm. C. B.)

PRÉVOST (D'EXILES), ANTOINE FRANÇOIS, Abbé (1697–1763), prolific French novelist whose fame rests entirely on his *Histoire du Chevalier des Grieux et de Manon Lescaut*, which was originally published as the final installment of a seven-volume novel called *Mémoires et aventures d'un homme de qualité qui s'est retiré du monde* (1728–31). This short work, which tells the story of a young man of good family who ruins his life for a courtesan, is a classic example of the 18th-century novel of feeling and the forerunner of the popular romances of later generations. It might in fact be described as a contemporary version of "boy meets girl." Its tranquil underlying assumption that love excuses the betrayal of every principle, its ingenious blend of innocence and depravity, and the skill with which an illicit relationship is invested with an aura of sentiment, explain why it has remained a best seller for over two centuries and why the authorities had it publicly burned as an immoral book when it first appeared in France.

Prévost was born at Hesdin, Artois, on April 1, 1697, of a prosperous middle-class family, and was the second of five sons, two of whom became priests. From an early age he displayed many of the weaknesses which are characteristic of the hero of his most famous work: susceptibility, impetuosity, inconstancy. His mother died when he was 14 and he was sent to the Jesuits' school in his native town. He claims, in the autobiography in the literary periodical he founded, *Pour et contre* (1733–40), that he ran away from school and joined the army before he was 16. After the Peace of Utrecht in 1713 he entered the Jesuit novitiate. He spent another brief period in the army in 1716, reentered the Jesuit novitiate in 1717, but left it again the following year. He was in serious trouble in 1719 and was obliged to ask the Society for sanctuary. He was eventually dismissed for reasons that are not known and in 1721 took his vows as a Benedictine monk at Jumièges. Some of his earlier escapades are believed to have been the result of quarrels with his father over women: in the autobiography he declares that he "buried" himself in the Order owing to the unhappy ending of a love affair. The next seven years were spent teaching, preaching, and studying at different Benedictine houses. He was ordained a priest in 1726 and two years later was at Saint-Germain-des-Prés, Paris, where he assisted with the writing of a historical work called *Gallia christiana*. Four volumes of his first novel, the *Mémoires et aventures*, were published in 1728. The same year he sought permission from Rome to transfer to a less strict branch of the order. Permission was granted, but Prévost was too impatient to wait for the official promulgation and left Saint-Germain without authority. A *lettre de cachet* (November 1728) was issued, and to avoid arrest he fled to England where he soon acquired an extensive knowledge of the language, history, and literature of the country, which was of considerable value to him in his later writings.

He left England abruptly in 1730 on account of another love affair which made it impossible for him to continue his work as tutor to the son of Sir John Eyles, a former governor of the Bank of England and member of parliament for the City of London. He spent the next three years in Holland with a mistress known as Lenki. The last three volumes of *Mémoires et aventures* were

published first at The Hague, then in Paris, in 1731. The same year saw the publication at Utrecht of the first four volumes of *Le Philosophe anglais, ou Histoire de Monsieur Cleveland, fils naturel de Cromwell*, in which he drew on his knowledge of England. This was completed in eight volumes in 1739.

During his stay in Holland Prévost was frequently in financial difficulties. In 1735 he and Lenki went to England to escape their creditors. Later that year he was imprisoned for a few days at the Gatehouse for forging the signature of his former pupil on a letter of credit and must be accounted fortunate to have escaped hanging. He returned secretly to France in 1734. Little is known about his religious beliefs during these years, but it has been suggested by C. E. Engel (*Le Vritable abbé Prévost*, 1958) that after leaving the Benedictines he was for a time a Protestant. On his return to France he was reconciled with the church and ordered to undergo a second novitiate, but though he was officially attached to La Grenetière, near Nantes, as Dom Prévost, he was dispensed from residence by becoming chaplain to the Prince de Conti. Although he obtained the living of the priory of Saint-Georges-de-Gesne in 1754, he does not appear to have performed any ecclesiastical functions. He continued his career as a man of letters, producing more novels, translations of Samuel Richardson, and other works.

With the exception of a short period of exile in Brussels and Frankfurt in 1741–42, Prévost spent most of his remaining years at Chantilly, where he died on Nov. 25, 1763.

Prévost's reputation as a one-book man does him less than justice. Although they are little read today, his *Histoire d'une Grecque moderne* (1740), which was based on the famous contemporary love story of the Chevalier d'Aydie and Mlle Aïssé (q.v.), and *Mémoires d'un honnête homme* (1745) are in some respects more mature and more impressive than *Manon Lescaut*.

BIBLIOGRAPHY.—The only collected edition of Prévost's works is the *Oeuvres choisies*, 39 vol. (1783–85). There is an English translation of *Manon Lescaut*, by L. W. Tancock (1949); and a critical edition, for the Textes Littéraires Français, by G. Matoré (1953). See also H. Harisse, *L'Abbé Prévost* (1896); P. Hazard, *Études critiques sur 'Manon Lescaut'* (1929); G. Poulet, *Études sur le temps humain* (1950); H. Roddier, *L'Abbé Prévost, l'homme et l'oeuvre* (1955); M. Turnell, *The Art of French Fiction* (1959). (M. Tu.)

PRÉVOST, (EUGÈNE) MARCEL (1862–1941), French novelist whose gifts of observation and subtle understanding of feminine psychology make his novels a witness to the changes in French bourgeois society between 1890 and 1920. He was born in Paris on May 1, 1862. After an education at Jesuit schools in Bordeaux and Paris and at the École Polytechnique he became a civil engineer in the Administration des Tabacs, but resigned in 1890 after the success of his first two novels, *Le Scorpion* (1887) and *Chonchette* (1888). From then on he gave himself up to the career of a popular novelist, remaining aloof from the literary schools and controversies of his time. Novel followed novel in a steady stream (52 in all); some of these he dramatized and they had a moderate success on the stage. His *Lettres à Françoise* (1902), *Lettres à Françoise mariée* (1908), and *Françoise maman* (1912)—books of wise counsel to young girls—were even more widely read than his novels. He was elected to the Académie Française in 1909. For some years after World War I he was director of the *Revue de Paris* and the *Revue de France*. He died at Vianne on April 8, 1941.

Prévost's first novel revealed the gifts which made him a favourite with a wide public. He was an analyst and realist, an unambiguous painter of the bourgeois life familiar to his readers. His novels were well constructed, skilfully maintaining interest in the development of a plot that was brought to a firm, dramatic conclusion. Their titles indicate their subject: *Confession d'un amant* (1891), *L'automne d'une femme* (1893), *Les Demi-Vierges* (1894; Eng. trans. 1895), *Les Don Juanes* (1922; Eng. trans. 1924), *La Maîtresse et moi* (1925; Eng. trans. 1927).

See *M. Prévost et ses contemporains*, 2 vol. (1943). (Em. H.)

PRIAM, in Greek mythology, son of Laomedon and last king of Troy. When Heracles captured Troy and killed Laomedon, Priam, still a boy, was saved. He succeeded his father. As king, he extended his control over the Hellespont. He married first

Arisebe, then Hecuba (*q.v.*), by whom he had many children, including his favourites Hector and Paris. Priam tried to avert the ruinous destiny of Paris (*q.v.*) by exposing the newborn baby; but when he survived his father took him back and thereafter seems to have played a passive role in the irresponsible actions which provoked the Trojan War. Homer describes Priam as an old man, powerless but kindly, not even blaming Helen for all his personal losses (*Iliad* iii, 161 ff.). Indeed, Homer treats Priam less as a king than as a father. In the final year of conflict, Priam sees 13 sons die, of whom Achilles kills Polydorus, Lycaon, and Hector within a day. The death of Hector, which signifies the end of Troy's hopes, also breaks the spirit of the king (*Iliad* xxii, 405 ff.). Priam's paternal love impels him to brave the savage anger of Achilles, to "kiss the hands of the man who killed his sons" and to ransom the corpse of Hector. In his trip to the Greek camp, Hermes guides Priam; Achilles, respecting the old man's feelings and foreseeing his own father's sorrows, ends his wrath by returning the corpse (*Iliad* xxiv, 322 ff.). Arctinus described the death of Priam, now best known from the version of Virgil (*Aeneid* ii, 507 ff.). When Troy falls, Neoptolemus butchers the old king on an altar. Both Priam's death and his ransoming of Hector were favourite themes of ancient art. (Wm. S. A.)

PRIAPEA, a collection of 85 or 86 short Latin poems in various metres, including hendecasyllables, choliambics and elegiacs, on the subject of the fertility god Priapus, who, with his sickle, protected gardens and vineyards against thieves and from whose axe-hewn image of figwood or willow protruded an erect, red-painted phallus. Though a few of the poems are inoffensive, the majority, despite occasional flashes of humour, are remarkable only for their obscenity. Most appear to belong to the Augustan age or to a date not much later and show evidence of indebtedness to Ovid. They in turn influenced Martial. Some may originally have been the leisure products of aristocratic voluptuaries; others, genuine inscriptions on shrines of Priapus. Donatus says that Virgil wrote some *Priapea*, and the first three poems of the *Catalepton* in the *Appendix Vergiliana* are of this genre; but, though Pliny says that Virgil composed "verses far from staid" (*versiculos severos parum*), there is no proof that these are Virgil's. In *Tibullus*, i, 4, an elegy of 84 lines, Priapus assumes the unique role of a professor of venery (*magister amoris*) and instructs the poet how best to secure the affection of the boy Marathus. A companion piece to this poem is Horace, *Satires*, i, 8 (50 hexameters), in which Priapus tells how he frightened away two witches from the site of the Esquiline cemetery when his figwood buttocks burst with a disconcerting pop. Martial's *Priapea* include epigrams 16, 49 and 73 in book vi, and 40 in book viii.

See F. Bücheler (ed.), *Petronius*, 6th ed. (1922). (H. H. Hy.)

PRIAPULIDA (PRIAPULOIDEA), a small group of wormlike marine animals formerly included in the obsolete phylum Gephyrea. Of uncertain affinities, they are now generally given phylum rank, though some authorities regard them as a class of the phylum Aschelminthes. There are two genera, *Priapulus* and *Halicryptus*, and at least eight species. They are drab coloured, small- to medium-sized (to about four inches long) cylindrical invertebrates, characterized by a superficially ringed body (not segmented) and a retractile proboscis. Priapulids burrow in the soft mud bottom by extending and retracting the proboscis; they capture and devour worms and other slow-moving prey. Priapulids are found in the cold seas of both northern and southern hemispheres, usually in coastal waters; abyssal specimens have been taken from great depths in both the Atlantic and Pacific oceans.

Structure and Function.—In *Priapulus* the surface of the muscular body wall is provided with rings of spines and papillae, the latter possibly sensory in function. The epidermis secretes a thick cuticle, which is shed at intervals during growth. There are 25 rows of spines on the surface of the proboscis, converging toward the mouth, which is itself surrounded by several five-toothed rings of chitinous teeth, features that gave rise to supposed echinoderm affinities. The mouth leads into a muscular, eversible pharynx, anchored by retractor muscles originating in the trunk. The cuticular lining of the pharynx is provided with

FROM THEEL, "NORTHERN AND ARCTIC INVERTEBRATES"

PRIAPULUS BICAUDATUS, A WORM-LIKE ANIMAL OF THE ARCTIC AND NORTH ATLANTIC SEAS

numerous small projecting teeth. The midgut is straight, and communicates with a short hindgut. The anus is either terminal or opens at the base of the hollow caudal appendages, present in *Priapulus* but not in *Halicryptus*. The body cavity, which in *Priapulus* extends into the ramifications of these gill-like appendages, is probably a true coelom, but its developmental homologies are unknown. There is no vascular system, but red cells containing hemerythrin, the same respiratory pigment as in Sipunculida, flow freely in the body cavity.

The nervous system, consisting of a circumesophageal ring and ventral nerve cord, retains its primitive connection with the ectoderm. There is no evidence of segmental ganglia. A visceral

plexus is connected anteriorly with the nerve ring.

The excretory system is protonephric; tufts of flame cells (solenocytes) discharge into the paired urinogenital ducts, which lie suspended in the body cavity and open posteriorly. The sexes are usually separate, but hermaphroditic individuals have been recorded; the gonads develop in the walls of blind evaginations of the urinogenital ducts. Fertilization is external. Segmentation by radial, nonspiral cleavage results in a hollow blastula and hatching occurs as a solid gastrula in which the outer ectodermal layer encloses an inner multinucleated mass. The eventual loricate larva has a spiny, retractile proboscis and a body protected by chitinous shields; in *Priapulus* larvae there are two pairs of feelers and a forked tail.

Relationships.—Resemblances to the gephyrean groups Sipunculida and Echiurida (*q.v.*) appear to be of a superficial nature, as are the similarities with sea cucumbers. The larvae have features in common with Rotifera, Kinorhyncha, and Gastrotricha (*q.v.*). Libbie Hyman placed the class Priapulida in the pseudocoelomate phylum Aschelminthes. K. Lang has suggested a close relationship with the Acanthocephala (*q.v.*), the spiny-headed worms. W. L. Shapeero has concluded that priapulids are true coelomates whose unique morphology qualifies the group for the status of phylum.

BIBLIOGRAPHY.—L. H. Hyman, *The Invertebrates*, vol. 3 (1951) vol. 5 (1959); H. L. Sanders and R. R. Hessler, "Priapulus atlantici and Priapulus profundus. Two New Species of Priapulids from 1173- and Abyssal Depths of the North Atlantic," *Deep-Sea Research*, 9:123-130 (1962); W. L. Shapeero, "Phylogeny of Priapulida," *Science* 133:879-880 (1961). (G. E. P.)

PRIAPUS, a god of animal and vegetable fertility in classical antiquity, whose cult was originally located in the Hellespontine regions, centring especially on Lampsacus, a city of which he was traditionally the chief deity. He was represented in a caricature of the human form, grotesquely misshapen, with an enormous and erect phallus. The ass was sacrificed in his honour. This is without parallel in Greek religious practice and attests the Oriental provenance of the cult, as does the myth that his mother was Aphrodite (doubtless to be equated with the Great Mother Goddess of the East). Ovid explains Priapus' hatred of the ass as being due to its braying when he was preparing to ravish the sleeping nymph Lotis, so that she awoke and escaped. The truth no doubt is that the ass symbolized lecherousness and was associated with the god's sexual potency.

Priapus' worship spread throughout the ancient world in hellenistic times, being popular in the great cities and establishing itself in Italy. This was too sophisticated an age for urban society to take Priapus very seriously and he was regarded rather with ribald amusement. In the country the situation was different; his statue was commonly found in woodlands, vineyards, fields,

and especially in gardens, though it was set up less with the idea of promoting the fertility of plants and trees, or of the cattle and bees which were also under Priapus' protection, than as a scarecrow to frighten away thieving birds or men. He was also the patron of seafarers and fishermen, and of others in need of good luck; his presence averted the evil eye. A series of short Latin poems in his honour (*Priapea*) has survived (see *PRIAPEA*).

See H. Herter, *De Priapo* (1932).

(D. E. W. W.)

PRIBILOF ISLANDS (*FUR SEAL ISLANDS*), islands of Alaska, including St. Paul (35 sq.mi. [91 sq.km.]), St. George (27 sq.mi. [70 sq.km.]), and two islets lying in the Bering Sea, about 300 mi. (480 km.) W of the mainland and 180 mi. (290 km.) N of Unalaska. They were first visited in 1786, by the Russian sea captain Gerasim Pribilof, who discovered their famous fur seal rookeries. Control of the islands was transferred from Russia to the United States with the purchase of Alaska in 1867. The population of the islands (1960) is 642 Aleuts and a few government officials.

Fur Industry.—The seals are a distinct species, the northern fur seal (*Callorhinus ursinus*), with fur superior to other species. They visit the Pribilofs from April to November. The older and stronger bulls gather harems; the younger "bachelors" congregate separately. By taking the "bachelors" when ashore, the herd may be conserved. However, sealing at sea (pelagic sealing) permits no selectivity, and half the animals killed are lost.

In 1870 sealing rights were leased to the Alaska Commercial Company. During the 1880s vessels of several nations engaged in pelagic sealing, and the islands' herds were vanishing. In 1886 U.S. vessels began seizing Canadian schooners sealing off the Pribilofs. A tribunal ruled against the United States in 1893. After 1910 the U.S. Bureau of Fisheries had direct supervision of the sealing.

In 1911 the United States, Great Britain (for Canada), Japan, and Russia signed the North Pacific Sealing Convention abolishing pelagic sealing north of latitude 30° N, and providing that each nation should share in the skins collected on the Pribilofs. The treaty was ended by Japan's withdrawal in 1941, on its contention that the seals were despoiling Japanese fisheries.

In 1957 an interim convention on conservation of North Pacific fur seals was signed between the U.S., Japan, Canada, and the U.S.S.R., which created the North Pacific Fur Seal Commission to supervise research. The herd increased from 125,000 in 1911 to about 1,000,000 by the 1950s. About 60,000 skins are harvested yearly. (See also *ALASKA: History: Diplomacy Involving Alaska; SEALING; SEA LION*.)

Natural History and Climate.—The islands are of volcanic origin. The flora is restricted to ferns, mosses, and grasses, creeping willows, and small shrubs. White and blue foxes, gulls, auks, and cormorants abound. The mean annual temperature is about 36° F (about 2° C). The rainfall is about 35 in. annually. Fogs are heavy and frequent.

(J. E. CL.)

PRIBRAM, ALFRED FRANCIS (1859–1942), Austrian-Jewish historian who after World War I contributed important knowledge of Austro-Hungarian policy before 1914. Born in London on Sept. 1, 1859, he studied in London and Vienna, and during 1894–1930 was professor of modern history in Vienna. Pribram's first interest was the 17th century; hence his book on Leopold I's diplomat *Franz von Lisola und die Politik seiner Zeit* (1894). After World War I, however, he turned to the period made prominent by the burning issue of war guilt, a subject for which he was well fitted by his natural objectivity and his background. He devoted himself mainly to the publication of state records. His works included *The Secret Treaties of Austria-Hungary 1879–1914* (English, German, French editions, 1919–23), *Austria-Hungary's Foreign Policy 1908–18* (1923), and *England and the International Policy of the European Great Powers 1871–1914* (1931). His lectures abroad also contributed to an understanding of Austrian prewar policy. He died in London on May 7, 1942.

PRICE, RICHARD (1723–1791), British moral philosopher, famous in his own day as a supporter of the American and French Revolutions and as an expert on insurance and finance, was born

at Tynton in Glamorgan on Feb. 23, 1723. The son of a dissenting minister, he himself ministered to English Presbyterian congregations in the vicinity of London, notably at Stoke Newington and at Hackney, where he died on April 19, 1791.

Price's *Review of the Principal Questions and Difficulties in Morals* (1758; third edition, enlarged, 1787) criticizes the moral-sense theory of Francis Hutcheson. It is one of the best statements of ethical intuitionism or rationalism, foreshadowing Immanuel Kant's ethics in some respects and 20th-century intuitionism in many (see *ETHICS, HISTORY OF: Modern Ethics*). In 1767 Price published *Four Dissertations*, including a reply to David Hume's essay on miracles, and, in consequence, received the degree of D.D. from Marischal College, Aberdeen. Price and Hume met and corresponded with mutual esteem. Another of Price's philosophical opponents, Joseph Priestley, was a close personal friend. They published jointly *A Free Discussion of the Doctrines of Materialism and Philosophical Necessity* (1778), doctrines which Priestley held and Price attacked.

Price was elected a fellow of the Royal Society in 1765 for work on a problem in the theory of probability, which he then applied to actuarial questions. *Observations on Reversionary Payments* (1771) laid the foundations of a scientific system of life insurance and of old-age pensions. It also recommended the reestablishment of the sinking fund to deal with the national debt, a proposal amplified in *An Appeal to the Public on the Subject of the National Debt* (1772). Price's views influenced French governmental policy through Robert Turgot and Jacques Necker and, later, British policy through Lord Shelburne (see *LANSDOWNE, MARQUESSES OF*), an intimate friend, and the younger Pitt.

Price was a friend of Benjamin Franklin and became a leading advocate of American independence. His *Observations on the Nature of Civil Liberty, the Principles of Government, and the Justice and Policy of the War with America* (1776) and *Additional Observations . . .* (1777) had an enormous sale in both England and America. He was given the freedom of the city of London in 1776, was invited by the U.S. Congress in 1778 to advise it on finance and was made LL.D., together with George Washington, by Yale College in 1781. Price welcomed the French Revolution in a celebrated sermon on *The Love of Our Country* (1789), to which Burke's *Reflections on the Revolution in France* was a reply.

BIBLIOGRAPHY.—Price published various other sermons and tracts. For his life and works see Roland Thomas, *Richard Price* (1924); and C. B. Cone, *Torchbearer of Freedom* (1952). The *Review of the Principal Questions in Morals* was edited by D. D. Raphael (1948). For discussion of that work see J. Martineau, *Types of Ethical Theory*, 3rd ed. (1901); W. H. F. Barnes, in *Philosophy*, vol. xvii (1942); C. D. Broad in *Aristotelian Society: Proceedings*, new series, vol. xlv (1944–45); D. D. Raphael, *The Moral Sense* (1947). (D. D. R.)

PRICE, THOMAS (1852–1909), Australian Labor politician, prime minister of South Australia (1905–09), was born at Brymbo, North Wales, on Jan. 19, 1852, the son of John Price, a stonemason. He was educated at a penny school in Liverpool, and became a stonecutter. Migrating to South Australia for his health in 1883, he again worked as a stonecutter, at one time being employed on the parliament buildings in Adelaide. He was secretary of the Masons' and Bricklayers' Society from 1891 until 1893, when he entered the colony's House of Assembly as Labor member for Sturt. From 1889 he led the Labor Party in Parliament and was premier and minister of education (1905–09) in the first stable Labor administration in Australia. He warmly supported full adult suffrage (including votes for women), the amelioration of factory conditions, and the protection of secondary industry, but his attempts to liberalize the franchise for the legislature's upper house, the Legislative Council, were successful only in part. He had a fervent Methodist belief in the need to regenerate mankind, and was an ardent advocate for temperance and for the diffusion of education. He died at Hawthorn, near Adelaide, on May 31, 1909.

See T. H. Smeaton, *From Stone Cutler to Premier* (c. 1910).

(O. M. R.)

PRICE, the measure of value of an article, or conventional unit of commodity or service, that expresses its worth in exchange for other goods. To effect such a measure some common unit of account is necessary. In fact, of course, any standard commodity

could be used; for example, if a yard of a given quality of cloth were chosen as the unit of account, the price of a pound of tea could be expressed as equal to, say, 3 yd. of cloth, or the price of a pair of shoes as 12 yd. of cloth. An economist would then say that the cloth price of tea was 3 and that of shoes 12. Alternatively, using tea as the unit of account, the tea price of cloth would be $\frac{1}{3}$ and that of shoes 4. Because of their durability and their value in terms of other goods relative to their bulk and weight, precious metals such as gold and silver have served mankind as standard commodities, as international currencies in effect, for thousands of years.

Today, in all but the most backward areas of the world, prices are expressed in terms of the national currency (U.S. dollars, English pounds, Argentine pesos, or fractions thereof), and the issue of notes and coins of convenient denomination is a government monopoly. The paper or metal itself on which is stamped some amount of the currency may have little material value, yet no creditor can lawfully refuse to accept such currency in full discharge of debts incurred. (See MONEY.)

Though there can, perhaps, be meaningful discussion of ethical rules for determining a socially "just" price, the economist's concern is almost exclusively with the prices that emerge under certain institutions, with special emphasis on their determination in a market economy. His interest ranges from movements in the price of one or two goods to those of virtually every price in the economy during some period, and he is concerned not only with particular prices in the real world but also with prices that exist only in some theoretical model. Again, the economist may be concerned either with the movement of prices relative to each other or with the general tendency of all prices to rise or fall together though in different degrees. Changes in the general price level are measured as movements of an index number, in the formation of which the key problem is that of attributing weights to the movements of the various prices that enter into the index. (See INDEX NUMBERS; PRICES, STATISTICS OF.)

It has been found convenient to separate the study of individual prices from that of the price level, despite their obvious relationship, and this dichotomy of treatment corresponds roughly with what has been called traditionally the theory of value on the one hand and monetary theory on the other. Using modern terminology, however, the determination of prices and quantities of individual goods is deemed the subject matter of microeconomic theory, while macroeconomic theory concerns itself with aggregates such as the levels of prices, output, and employment.

As a rule, microeconomic theory treats of the determination, under given conditions, of the relative prices of a number of goods. If only two goods were being studied, there would be only one relative price, or price ratio (ignoring reciprocals); if three goods, three price ratios; if four goods, six price ratios; and so on. In theories that purport to explain the formation of all prices in the economy—sometimes referred to as general equilibrium systems—the practice has been to minimize the number of price ratios by choosing one good as *numéraire*, its price being, by definition, equal to unity, and expressing the price of each of the other goods as the number of units of the *numéraire* for which it exchanges.

Such prices are sometimes referred to as "real" prices, and they can be translated into a system of money prices by the simple expedient of attributing a money price to the *numéraire*. Though whatever money price is chosen does not, of course, affect the pattern of the real prices, it still cannot be chosen arbitrarily. It must be at a level high enough to make people satisfied to hold the stock of money in existence. (See QUANTITY THEORY OF MONEY.)

Movements of the general level of money prices are of particular interest in connection with theories of inflation and deflation and the study of cycles of prosperity and depression. It is a well-known phenomenon that some groups of prices move faster than others; in a boom, for example, prices of equities rise fastest, followed by wages, salaries, and rents in that order (all these can be regarded as prices; see below).

Price Determination.—The demand price of a good is the maximum price at which, under specified conditions, some particular quantity of it would be bought during a given period. Variation

of this quantity, and also therefore of the corresponding price, generates what is known as the demand schedule or, when constructed diagrammatically, the demand curve (price being measured along the vertical coordinate and quantity along the horizontal coordinate). Alternatively, any point on this curve exhibits the maximum quantity demanded at the corresponding price, this quantity growing, as a rule, as the price declines.

The supply price of a good is the minimum price at which, under specified conditions, some particular quantity of it would be supplied during a given period. Variation of this quantity, and also therefore of the corresponding supply price, generates a supply schedule or, diagrammatically, a supply curve. Such a supply schedule, or supply curve, is commonly defined as the minimum price at which an industry (composed of profit-maximizing firms) would make available to the market a continuous range of quantities of the good in question, either in a short period during which there was no time to alter plant and equipment or in a long period in which there was time enough for all factor prices (see below) to change and for industry to alter fully all its capital equipment. According to the prevailing technical conditions and the given resources of the economy the supply curve can assume a variety of forms. Although in short periods it normally rises as the quantity increases, in periods long enough for full adjustments to be effected it may rise, remain constant, or (especially if there are large economies of scale) decline as output expands.

An "offer curve" is sometimes referred to as a supply curve, though it is concerned not with the cost of production of a good but with the offer from a single person, group, or country of productive services, or of goods from existing stocks or from given inflows, in response to the price. The price-quantity relationship has to be interpreted here as tracing the maximum quantity that would be supplied at any one of a continuous range of prices. (The minimum price definition of the preceding paragraph may, however, be extended to offer curves also, provided the condition is imposed that, in moving along this offer curve, the welfare of each supplier remains unaltered. In general, this definition yields an offer curve somewhat larger than that constructed under the first definition.)

The equilibrium price is the price which, under specified demand and supply conditions, has no tendency to change. An elementary economic proposition lays it down that a necessary condition for an equilibrium price is that it be one at which the respective quantities of the relevant demand and supply schedules are equal. (See SUPPLY AND DEMAND.)

A competitive price is the price ruling in a market in which there is a large number of competing suppliers, and entry into which is unimpeded. The extreme case, or ideal model, of such a market is spoken of as "perfect competition," a market form in which it is supposed that all producers, as well as all consumers, accept the market price as being beyond their resources to influence, since the quantity supplied or demanded by any one person or firm is a negligible proportion of the total. A corollary of such competition is that the market price tends to equal the lowest unit cost of the most efficient producer, as any positive profit (revenue to the firm in excess of payments to the factors of production) attracts new firms into the industry. (See COMPETITION ECONOMIC.)

A monopoly price is the price set by the sole producer of a good, or by a group of producers of a good acting together. If the monopolist is regarded as producing the output which maximizes his profit, the price corresponding to that output can be shown to exceed his marginal cost (the additional cost of producing an extra unit of output), this excess being greater the fewer the substitutes there are for the monopoly good. A discriminating monopolist can set different prices for markets that are separated by distance or tariff barrier, though obviously such differences cannot exceed the unit cost of transport and duty in sending the goods from one market to another. Acting within this constraint, however, the enterprising monopolist sets the price higher in markets that are less responsive to price changes. (See MONOPOLY)

Other Prices.—Passenger fares and freight rates are, of course, prices of services rendered. Foreign exchange rates express the

prices of foreign currencies in terms of the domestic currency, or vice versa. The spot price of a currency, or spot rate of exchange, refers to the rate of exchange between two currencies for a current transaction. The forward price of a currency, or the forward rate of exchange, is the rate of exchange currently agreed between two parties for the exchange of stated amounts of two different currencies at some designated future date—usually from one to three months, and seldom more than six months, from the current date. Similarly, the price of futures is the current price at which some standard grade of a commodity, such as grain or cotton, may be bought or sold for delivery and payment at some designated future date.

Factor prices are the returns paid for the services of the agents of production classified either narrowly or broadly. In the classical tripartite division of the factors of production, wages are the price of the services of labourers, rent is the price paid for the use of land (or of other resources, or assets, having the essential nondepreciating characteristic of Ricardian land), and interest is the price paid for the services provided by loans. Profits, however, are not regarded as the price of any productive service, or factor, but as a residual after all the firm's contractual payments have been met. They may be justified as the reward of bearing uninsurable risks in business, and are an index of the success of the enterprise in responding to opportunities provided by changing market conditions. See PROFIT; VALUE. See also references under "Prices" in the Index. (E. J. M.)

PRICE MAINTENANCE, a term applied to the measures taken by individual manufacturers or distributors of specific branded, trademarked goods to protect the retail prices of their products and eliminate price-cutting. The legal status of resale price maintenance varies from one country to another and in the United States from one state to another. See FAIR TRADE LAWS.

PRICES, STATISTICS OF. In the United States, the United Kingdom, and some other countries, price quotations for important commodities are available from early in the 19th century; there are also a few quotations from earlier periods. In general, during these long intervals of time, there have been many changes in the nature and quality of the commodities and in the type of price quotation; sometimes, however, the changes have been small enough to permit the compilation of a continuous series of prices on a reasonably comparable basis. Nevertheless, a few series of prices of single commodities cannot be taken as a description of general movements in prices. What is required for this purpose is a set of indicators showing the general course of prices, in convenient major groups of commodities, over a period of time in a particular country. Such indicators can be constructed only in the form of index numbers (see INDEX NUMBERS), which are generally averages of the changes in prices of certain commodities selected to represent the various groups. The averages can be computed in various ways to give different results. Moreover, the index numbers depend on the accuracy and continuity of the price quotations used, and any one compilation is generally limited to comparisons of prices in a relatively short period, perhaps no more than 10 or 20 years. For longer-run comparisons, different index numbers need to be linked together, and the results are then still more approximate.

The most obvious feature in the general world picture is the effect of major wars on wholesale prices. During the French Revolutionary and Napoleonic Wars (1792–1815) prices rose rapidly and were then maintained at a high level for some years, though with considerable oscillations. Prices fell after Waterloo, but it was not until the 1820s that they had dropped to the level of the years before 1792. The American Civil War (1861–65) gave rise to the second major peak in wholesale prices in the United States, but the effect in the United Kingdom, and in many other countries, was much smaller. World Wars I and II exercised an even sharper effect on prices. Moreover, at least in the United Kingdom and the United States, the course of prices was broadly similar during and immediately after the two wars: an immediate and pronounced rise early in the war, followed by a slower increase as measures of price control became effective, and then another sharp rise after the close of hostilities. The main differences

between the two wars were that price control was effective sooner in World War II and the postwar increase in prices was more protracted.

Between wars the trend of prices was generally downward and, at the outbreak of one war, the level of prices was little different from that immediately before the previous war. Closer inspection, however, reveals major fluctuations in the general course of prices. One cause of disturbance was the discovery of new goldfields or the rapid development of gold production. A growth in the supply of gold coming forward pushes up prices in domestic currencies that are based on gold. The discovery of gold in California and Australia raised wholesale prices after 1850, and prices did not sink below the level of 1849 until about 1890. In the United States the steady decline in prices after the Civil War led to acute agrarian discontent and the demand for increased coinage epitomized by William Jennings Bryan's campaign for the presidency in 1896. The development of the goldfields in Alaska and South Africa was the main influence in the steady rise in prices following the low point reached in 1896, a rise which continued until the outbreak of World War I.

Other major fluctuations, generally working themselves out in a period of less than ten years, are those associated with booms and depressions. The pattern includes four steps: boom, commercial crisis, recession, and recovery. Commercial crises generally appear as peaks in the course of wholesale prices; e.g., those of 1839 and 1847 in the first half of the 19th century and that of 1907 at the beginning of the 20th. No earlier depression, however, had quite the same catastrophic effect as that following the crisis of 1929. Both in the United Kingdom and in the United States wholesale prices in 1929 stood about 35% higher than in 1913; by 1932–33, prices had fallen to nearly 10% below the 1913 level; i.e., a decline of one-third in less than four years.

A remarkable feature of the course of prices in modern times is the broad similarity between the movements in the United Kingdom and the United States (cf. fig. 1 and fig. 2). There are, of course, many factors which exert little more than a local influence. However, major wars, severe commercial crises, and gold discoveries are events which are international in their impact on economic affairs and they affect prices everywhere. For this reason it can be said that there has been a level of world prices, the movements of which can be distinguished in a broad historical survey.

In an index of the general level of wholesale prices, the movements in the prices of commodities of many different kinds are averaged. Individual price quotations are to be expected to show greater fluctuations than the general average, as is well illustrated by the price of English wheat. Until about 1880 imports of wheat into the United Kingdom were small, and the price was largely dependent on the supplies of domestic wheat available and hence on the size of the harvest. The price of wheat showed very large fluctuations, many of which did not correspond at all with movements in the general price level. After 1880, with increasing supplies of wheat arriving from the Western Hemisphere and other overseas areas, the price of English wheat was determined more by world prices than by the British harvest. The results were, first, that the price was reduced in relation to other prices and, second, that there were less violent fluctuations in price. Though still showing wider variations than the general price level, the price of English wheat followed fairly closely the general course of prices. (R. G. D. A.)

UNITED STATES

In the United States, as in other countries, statistics of prices became available in greater quantity and in more varied forms than data reflecting other major aspects of the economy such as production and employment. The quantity of price data was steadily enhanced by the contributions of government departments and private business and research groups, and historical information about prices and price movements was expanded by the painstaking work of individual scholars.

Problems.—Statistics on prices are available in two forms: (1) price quotations for specified commodities, services, or securities;

and (2) index numbers, which usually are designed to summarize the average amount of change in the prices for a specified group of commodities, services, or securities between two or more dates. Despite the careful efforts of price statisticians in business and government who supervise the collection of price data and the compilation of price indexes, the numerous practical and theoretical difficulties involved in their work cannot be completely overcome. Although these problems need not be considered in detail here, some understanding of their general nature is essential to proper interpretation of price data.

The central problem of price collection is to gather a sample of prices representative of the various price quotations for each of the commodities under study. Sampling is almost always necessary because it is not feasible to obtain a record of every single transaction. Price collection must be planned so that observed differences between the prices of any two dates (any two places, when place-to-place rather than time-to-time price differences are being studied) will reflect changes in price and price alone. In order to exclude the influence of variation in quality, commodity prices are frequently collected in accordance with detailed specifications (*i.e.*, descriptions) such as "wheat, no. 2 red winter, bulk, carlots, f.o.b. Chicago, spot market price, average of high and low, per bushel."

When the correct average prices for a commodity for successive dates have been determined, they may be expressed as percentages of the price for a particular date or "base period." These percentages are called "price relatives." The problem of constructing price index numbers is to combine either the prices themselves or the price relatives in such a way that the central tendency of the movement of the whole group of prices from one period to another is accurately described. Although a number of problems are encountered at this stage, the one that is perhaps the most important to an understanding of the limitations of price indexes is the weighting problem. This arises because not all commodities for which prices have been obtained are of equal importance in the price universe under study. The price of wheat, for example, should be given more weight in an index of wholesale prices in the domestic economy than the price of pepper, because wheat is much more important in trade. The difficulty is that the relative importance of commodities changes over time. Furthermore, some commodities drop out of use and new ones appear, and often an item changes so much in composition and design that it is doubtful whether it can properly be considered the same commodity. Under these conditions, the pattern of weights selected can correspond accurately to the relative importance of the various commodities in only one of the periods for which the index numbers have been calculated. The greater the lapse of time between the period of the weighting pattern and other periods, the less relevant the pattern is likely to be for one of the periods, and therefore the less meaningful the price comparisons become. Price indexes thus can give relatively accurate measures of price change only for periods close together in time. F. C. Mills found also that the dispersion of price relatives computed on a given base year tends to increase with time; this means that the price index numbers becomes less representative of the central tendency of the whole distribution of the price relatives for the various commodities.

Sources of Data on Actual Prices.—The most important single source of price statistics in the United States is the Bureau of Labor Statistics (BLS) of the U.S. Department of Labor. In the early 1960s the BLS published monthly prices (at the wholesale level) for about 1,000 different commodities and (at the retail level) for almost 100 foods and for various types of fuels. The prices were generally those prevailing on the Tuesday of the week in which the 15th of the month fell. All the retail prices and the great bulk of the wholesale prices were obtained directly from sellers. Most retail prices were collected during store visits by price agents trained to price goods in accordance with established specifications. A few retail prices, such as those for fuel, were obtained directly from sellers by mail. The other primary market prices were obtained mainly from such recognized trade journals as *Iron Age* and the *Oil, Paint, and Drug Reporter*.

Another important governmental source of price data was the Department of Agriculture, which collected both local market prices and wholesale prices of farm products, the latter referring to prices at central markets. Estimates of Dec. 1 crop prices and Jan. 1 farm values of livestock have been available since 1867; monthly prices of commodities sold by farmers have been available since 1908 or 1910. Prices of articles bought by farmers were published annually from 1910 to 1922 and quarterly (for most items) thereafter. By the 1960s the department was receiving reports on farm product prices from about 9,000 respondents (mostly buyers or dealers) and reports on prices paid by farmers from about 17,000 respondents (mainly independent retailers serving the farm population). The prices thus obtained were made available in the department's publication *Crops and Markets*.

The trade journals were the most readily available nongovernmental sources of commodity price data. Prices for highly standardized commodities traded on organized markets (*e.g.*, wheat, coffee, and sugar) and prices for stocks and bonds were also reported in the financial pages of many metropolitan newspapers.

In 1960 the prices collected by government agencies and the indexes derived from them were subjected to the careful scrutiny of an expert committee headed by George J. Stigler. (*The Price Statistics of the Federal Government*, National Bureau of Economic Research, General Series, Number 73, 1961.) The Stigler committee made some important suggestions for improving the price data collected both by the BLS and the Department of Agriculture. It expressed doubts about the validity of the BLS reliance upon sellers for price information, particularly in connection with wholesale prices, in the following words:

In summary, the evidence that the BLS company price quotations are not valid transaction prices is highly persuasive. The quotations now collected are at best the initial base for negotiation in many cases, and often represent only the hopes of sellers or the snares of inexperienced buyers.

We recommend that a major shift be made to the collection of buyers' prices.

These remarks were based largely upon a staff study that showed that actual prices paid by the purchasing departments of government agencies were lower and were characterized by more frequent and wider fluctuations than prices for the same products that were reported to the BLS. However, the long-run movements of prices as revealed by the BLS data were probably less vulnerable to this criticism. The main shortcoming of the Department of Agriculture's price data, in the view of the committee, was that the products for which prices were collected were not narrowly enough defined; the data actually obtained represented the average values of a broad range of qualities rather than the prices of specified qualities. It should be stressed that the Stigler committee's criticisms of the price work of the federal government were based upon a very high professional standard of excellence. In quality as well as in quantity, the U.S. has price statistics that are seldom if ever excelled.

The Consumer Price Index.—The prices from all these sources were used to compute a wide variety of price index numbers. The most generally used index numbers were those computed by the U.S. government, particularly the consumer price index and wholesale price index. The consumer price index prepared by the BLS is probably the one that is best known to the average American. It measures the changes in prices paid by families of wage earners and low-salaried workers living in cities. The average size of the families included was about 3.3 persons in 1953, and the average family income was \$4,160 after taxes (Families with after-tax incomes in excess of \$10,000 in 1950 were excluded.) The types of families included represented about 64% of the urban population and about 40% of the total U.S. population. A further revision of the index, effective in January 1964, extended its coverage to include all urban families which derived at least 50% of their total income from wage and clerical occupations (dropping the former overall \$10,000 maximum) and to include also single workers living alone.

The quantity of commodities and services purchased by city

wage-earner and clerical-worker families is determined from time to time by sample surveys of their expenditures. In 1950, for example, about 8,000 such families were asked detailed questions about their expenditures for food, clothing, housing, medical care, etc., and another such survey was undertaken in 1961-62. From these surveys, the sample of items and the weights to be assigned to each are chosen. After the 1950 survey the index was computed from the price movements of about 300 items, including 90 foods, 75 articles of apparel, 35 housefurnishings, and 10 fuels. In the 1964 revision the sample of items was extended to 400 items. Prices for each item were collected according to detailed specifications to ensure that price differences between two periods reflected pure price movement and not changes in quality. Prices were collected in a sample of more than 16,000 outlets in 50 representative urban areas. In each community the BLS tried to obtain prices from a sample of stores that would represent the shopping pattern of the families of wage earners and clerical workers. Food prices and the prices of a few other items which change frequently were collected every month in each city, but prices for other commodities and services were collected monthly only in the five largest cities and every three months in the other cities. The prices generally refer to the middle of the month, and most of them are collected by visits of field agents to stores. From these prices two types of indexes are computed, one representing all urban areas of the U.S. and another representing each of 17 large cities. Each index is a weighted average of price changes. Beginning with the January 1962 index number, the base of the consumer price index was shifted from 1947-49 to 1957-59 in accordance with the recommendations of the U.S. Office of Statistical Standards. In addition to the comprehensive index for all items, separate indexes were published for five major categories (food, housing, etc.), for more than a dozen subgroups (dairy products, rent, etc.), and for a large number of minor products. Separate indexes were also available for a number of special groupings (commodities versus services, durable versus nondurable commodities, etc.). The indexes are published in a special monthly release of the Bureau of Labor Statistics; they appear also in the *Monthly Labor Review* and *Survey of Current Business*.

The consumer price index had its origins in World War I, and the official series began with data for 1913. Although historical research has produced consumer price indexes (or cost-of-living indexes, as they used to be called) for the 100 years preceding the beginning of the BLS series, most of these estimates are based mainly on wholesale price changes. Several of these indexes were linked together by the Federal Reserve Bank of New York to form a single series for the period 1820-1913.

A factor that heightens public interest in current index numbers is their use in escalator clauses in labour-management agreements. Such clauses, which covered between 2,000,000 and 4,000,000 employees in the early 1960s, provided for automatic changes in wages when the index moved up or down.

The Stigler committee was concerned lest the important economic interests thus involved in the consumer price index institutionalize the index and hamper improvements in it. The committee felt that use of the index for wage escalation should not be permitted to prevent the development of a broadened consumer price index that would cover the entire population, including persons living in rural areas, single persons, and high-income families in urban areas. Such a comprehensive index is the one that is relevant to the broad analytical uses that the consumer price index should serve—for example, to aid in measuring changes in the national welfare and in measuring inflation (and thus providing guidance for monetary and fiscal policy).

Another problem affecting the preparation of the consumer price index is the treatment of new goods and changes in the quality of old goods. One school of thought, favoured by the government technicians who prepare the consumer price index, is that the index should be primarily a price index measuring the changes in the prices of a fixed "basket" of goods. A second position, held by the Stigler committee, is that the consumer price index should measure the changes in the cost of buying a constant bundle of satisfactions or utilities. Even, for example, if coal remains un-

changed in price, the consumer benefits if he can heat his house more cheaply with a newly available supply of natural gas. The BLS price index would show no decline in price as a result of the availability of a cheaper fuel, but an index measuring the cost of a constant bundle of utilities would show a decline reflecting the reduced cost of house heat. Conceptually, there is little doubt that the constant-utility index is superior for virtually all of the analytical purposes for which indexes are used, but there are great difficulties in the path of calculating constant-utility indexes by objective methods that would command wide support and confidence. The practical importance of this issue arises from the fact that the continual improvement in the content and quality of living through the development of new and better products may have led to an overestimation of the extent of price increases and to an underestimation of the extent of the increase in the real volume of production. The two schools of thought tend to differ also upon the quantitative importance they assign to these potential biases.

The Wholesale Price Index.—The wholesale price index, also prepared by the BLS, is less well known to the average person but is more widely used in the business world than is the consumer price index. The BLS official wholesale price index numbers date from 1890. As in the case of the consumer price index, the methods of computation and the commodity composition of the index have changed from time to time, but the revisions were made so as to minimize the adverse effects upon the comparability of the series. The number of commodities included in the index expanded from 250 at the beginning to about 2,200 in the 1960s. The new commodities tended to be more highly fabricated and to have more stable prices, and they therefore tended to dampen the fluctuation in the index. One reason for the expansion of the list of commodities included in the index was a gradual shift in the conception of the function of the index. Originally, the index was regarded as a measure of movements in the general price level, but as other indexes such as the consumer price index and the implicit national income deflators (*see below*) became available, less reliance was placed on the wholesale price index for this purpose. At the same time there was a growing demand for subindexes pertaining to particular classes of products for various business and analytical purposes. Thus the nine major categories for which separate price indexes were originally published (farm products, foods, cloth and clothing, building materials, etc.) were more finely divided. In the middle 1960s monthly price indexes were being published for 15 categories, nearly 100 subgroups (e.g., fresh fruits, grains, etc.), and a large number of product classes (e.g., apples, bananas, barley, corn, etc.). Indexes were also available for the commodities classified according to stage of processing (crude materials, intermediate materials, and finished goods), according to the durability or nondurability of the products (e.g., food versus steel), and according to the economic sector for which goods were intended (e.g., consumers, producers, etc.). In addition, there were more than 50 indexes for special commodity groups, about half of which were for various categories of pharmaceutical preparations. A survey of the users of the wholesale price index indicated that the detailed information about price movements for individual industries, product classes, and commodities was most valued, especially by business firms and trade associations. Of course, the comprehensive monthly index number embracing all commodities is still used as an important indicator of the general movement of prices in the economy, particularly since the implicit deflators of gross national product (which because of their comprehensiveness are conceptually superior for this purpose) are available only on a quarterly basis and then only with a time lag of several months. The utility of the wholesale price index as a general price indicator is enhanced by a weekly index which is intended to provide an estimate of what the monthly index would be if it were computed each week. After 1952, the weekly index was no longer corrected after its issuance to make it conform to the movement shown in the monthly index. The BLS also publishes a daily index of spot market prices, intended to serve as a sensitive gauge of changes in market conditions.

FIG. 1.—MOVEMENTS OF WHOLESALE COMMODITY PRICES IN THE UNITED STATES, 1790-1960 (1947-49 = 100). FROM 1790 TO 1889 THE WARREN-PEARSON-STOKER INDEX (STOKER BEFORE 1797) IS USED; FROM 1890 TO 1960 THE OFFICIAL INDEX OF THE BUREAU OF LABOR STATISTICS IS USED

The wholesale price index represents the price movements of all commodities flowing into primary markets of the U.S.—whether domestically produced or imported. Primary markets are those in which a good in a given stage of fabrication is first sold in substantial quantities. Since the index includes the primary market prices of goods of all degrees of fabrication, the same commodity is often priced at several stages of processing. For example, cotton is priced in the form of raw cotton, cotton yarn, cotton gray goods, cotton piece goods, and cotton clothing.

Each commodity at each stage of production enters into the index with weights corresponding to the value of shipments of the commodity itself plus that of other commodities of a similar character that are not priced but whose prices are known or assumed to move similarly. Usually the weights for unpriced items are assigned—or “imputed”—to commodities with a similar manufacturing process. The BLS makes periodic revisions in weights as new industrial censuses become available. The index is calculated as a weighted average of price changes. Like the consumer price index, it was shifted to a 1957-59 base beginning in January 1962.

The full array of prices and price indexes is published in a monthly publication entitled *Wholesale Prices and Price Indexes*, but for most users the degree of detail appearing in the *Monthly Labor Review* and the *Survey of Current Business* is adequate.

The BLS wholesale price index was extended back to 1801 on the basis of price indexes for 1801-40 computed by A. H. Hansen (*Publications of the American Statistical Association*, pp. 804-812 [December 1915] and *BLS Bulletin No. 367*, pp. 235-48) and data for 1841-89 contained in the Aldrich committee's comprehensive report, “Wholesale Prices, Wages and Transportation,” *Senate Report No. 1394*, 52nd Congress, 2nd session, part i, p. 9. Hansen's data were based on prices published in Boston newspapers for the period 1801-25 and for the period 1825-40 on New York prices published in the “Report of the Secretary of the Treasury on the State of Finances” for the year ending June 30, 1863.

The BLS index was also extended back to 1797 by G. F. Warren and F. A. Pearson and to 1720 by H. Stoker. This work was based primarily on New York City prices obtained directly or indirectly from newspaper sources and from the treasury report mentioned above.

Implicit Price Deflators.—The development of statistics of national income and gross national product gave rise to measures of price change—often referred to as implicit price deflators—

that are more comprehensive than either the consumer or the wholesale price index. Once statisticians succeeded in compiling estimates of gross national product in terms of current prices (i.e., the prices prevailing in each year), they turned their attention to estimating these aggregates in terms of constant prices (i.e., estimating the gross national product, for example, for a whole succession of years in terms of the prices of a single year). This step was necessary if the figures were to reveal how much of the observed time-to-time change in gross national product was a real change in physical output and how much represented merely a change in prices. This work was done by expressing each detailed component of gross national product in terms of the prices of the selected base year, a result that was achieved by “deflating” the current value series by some appropriate price index. For the most part, the detailed BLS price series, both consumer and wholesale, were used for this purpose, but a wide variety of other price information was also employed. When these detailed “deflated” components of gross national product are added up, the result is an estimate of gross national product in terms of base period prices. Early in the 1960s, for example, the Department of Commerce, which produces the national income and product statistics, was publishing the data in terms of both current prices and 1954 prices. There is, of course, a comprehensive price index implicit in the comparison of the current and constant-value series. For example, from the fact that the 1961 gross national product was \$521.3 billion in current (i.e., 1961) prices and \$448.9 billion in 1954 dollars, an implicit price index of 116 can be computed ($521.3 \div 448.9$, all multiplied by 100) for 1961 on a 1954 base.

Implicit price deflators provide a generally superior measure of the overall behaviour of prices because they are more comprehensive than either of the major indexes previously discussed and because they refer to a universe that can be more readily defined than that of the wholesale price index. However, they are available only on a quarterly and annual basis, and the other indexes thus are still used as month-to-month indicators of price behaviour.

Implicit price indexes are available for the period since 1940 for 10 categories of consumption, 14 types of construction, and 21 groups of producers of durable equipment. (See U.S. Department of Commerce, *U.S. Income and Output*, pp. 220-229.) On a current basis they are available in summary form in each issue of the *Survey of Current Business* and in more detail in the July issue each year. The Department of Commerce has computed implicit deflators in a somewhat lesser degree of detail also for the period

1929-46 (*National Income, 1954 Edition*, pp. 216-217), and Simon Kuznets and others have estimated implicit price indexes back into the 19th century (S. Kuznets, L. Epstein, and E. Jenks, *National Income and Its Composition, 1919-38*, pp. 141 ff., 1941; and S. Kuznets, *Capital in the American Economy*, pp. 511 and 561-566, 1961).

An earlier attempt was made by Carl Snyder to develop an "index of the general price level." Snyder's index was designed to measure changes in the prices of commodities at all levels from primary to retail markets and shifts in the prices of services and property as well as of commodities. The index was extended from 1938 back to 1791. (*Review of Economic Statistics*, February 1934, p. 25 and February 1928, p. 40.)

Indexes of Prices Paid and Received by Farmers.—The indexes of the prices paid by farmers and of the prices received by farmers are unique because they have become so deeply involved in the political processes of federal support for agriculture. Both indexes were first published in the 1920s when a 1909-14 base was logical enough. When the Agricultural Adjustment Act of 1933 was passed, an attempt was made to establish "parity" prices for basic farm products so the farmers' income would have the same purchasing power it had in the 1909-14 base period. At the same time the first steps were taken toward the legislative control of the indexes. Legislation on the books in the 1960s required among other things that the 1909-14 base be retained and that farm-wage rates, farm taxes, and mortgage interest per acre be included in the "prices paid" index. The political importance of the indexes not only solidified practices that were questionable on technical grounds but also inhibited the normal processes of revision and improvement that would otherwise occur.

Export and Import Price Indexes.—With the gold losses that the U.S. suffered in the late 1950s, attention turned to relative price movements as a possible explanation for the continuing deficit in the U.S. balance of payments. Many people were surprised to learn that the U.S. had no real price indexes for exports and imports. The closest approximations were unit value indexes produced by the Bureau of Foreign Commerce in the Department of Commerce. A unit value index differs from a price index in that it measures the changes in the average value per physical unit regardless of whether the change is due to a change in price or to a change in size, quality, or other circumstance. Unit value indexes are relatively easy to compute; the development of true price indexes requires much greater resources of money and personnel.

Unit value indexes are calculated for each of five broad commodity groups of U.S. exports and imports, ranging from crude materials to finished manufactures, and, of course, for total exports and imports. The indexes go back to 1913 and have been available on a monthly basis since 1933. Unlike the BLS indexes discussed above, which have fixed weights, the unit value indexes are constructed by Fisher's ideal index number formula; that is, each index represents the square root of the product of base-year weighted and given-year weighted indexes.

Other Indexes.—Although the steady improvement in the scope and quality of the price work of the U.S. government has brought about a gradual decline in the number of general purpose indexes produced under private auspices, a large number of special-purpose price indexes are still computed for particular firms, especially in connection with their marketing or purchasing activities, and by trade journals. *Iron Age*, for example, publishes an index of finished steel prices, a weighted average of the prices (in cents per pound) of ten major finished steel products.

Aside from the services included in the consumer price index, the most readily available indicators of the changing price of services were indexes of hourly earnings and wage rates. The BLS series on average hourly earnings of production workers in manufacturing industries, available since 1909, was the most general of these series. Indexes of wage rates were restricted to particular groups of workers such as organized workers in the building and printing trades.

A field in which it was necessary to combine wages and commodity prices to derive indexes was construction. These were not

price indexes in the strict sense, but construction-cost indexes. A number of these indexes were published in the 1960s by private business groups; in addition, government agencies published index numbers of construction costs in such fields as railroad, highway, and farm construction. Most construction-cost index numbers went back to the 1910-13 period. In addition to the implicit deflators for various types of construction to which reference has already been made, construction-cost indexes were prepared by *Engineering News-Record*, the American Appraisal Co., the Associated General Contractors of America, Inc., and E. H. Boeckh and Associates, Inc.

The last category of price indexes requiring consideration here consists of the indexes of security prices. Among the leading indexes of stock prices in the 1960s were those prepared by the New York Stock Exchange; Moody's Investors Service, Inc.; Standard and Poor's Corp.; and Dow, Jones & Co. The first of these indexes was based on the average price obtained by dividing the market value of all listed stocks at the end of the month by the number of shares. The other indexes were based on a more limited but more constant group of sample stocks selected to represent different groups of stocks. The Dow-Jones averages, for example, were based on 30 industrials, 20 railroads, and 15 utilities; the Standard and Poor's indexes, based on 400 to 500 stocks, were available for a more detailed industrial classification. Indexes of bond prices were also computed by the New York Stock Exchange, Standard and Poor's, and others; such indexes generally derived the bond prices from average yields.

The general user of price indexes may find data for almost all of the price index series mentioned above in *Survey of Current Business*, a monthly publication of the Department of Commerce. An excellent source of information about historical price statistics, going back to the 18th century in some cases, is *Historical Statistics of the United States, Colonial Times to 1957: a Supplement to the Statistical Abstract of the United States*. The biannual publication of the Department of Commerce entitled *Business Statistics* gives the price series currently published in the *Survey of Current Business* for each year of the two most recent decades and for each month of the four most recent years. (I. B. K.)

UNITED KINGDOM

The movement of the general level of wholesale prices in the United Kingdom during the 19th century, between the close of the French Wars and the South African War, can be summarized best by reference to three periods. Between 1820 and 1850 there was a general downward movement, combined with considerable fluctuations, from about 155 in 1820 to about 90 in 1850 (1913 = 100). From 1850 to 1875 the price level was first raised and then maintained, apart from fluctuations, as a result of great economic developments (in industry, transport, etc.) coupled with the new supplies of gold from California and Australia. The earlier downward trend was resumed after 1875, when the level was around 115 (1913 = 100), until a low point of little more than 70 was reached in 1896. Wholesale prices generally fell by half in the 75 years after 1820. (See fig. 2.)

From this low point wholesale prices moved upward slowly but fairly steadily until 1914. The immediate effect of the outbreak of World War I was a sharp rise in prices. Control of prices began to moderate the rise toward the end of 1917, and there was even a short-term decline after the Armistice in 1918. The postwar rise of 1919-20 was the most rapid recorded to that date and the reaction of 1920-21 was just as spectacular. Wholesale prices increased by more than 40% in the year ended April 1920 and were then halved by the end of 1921. The subsequent fall until 1929 was the result in part of the restoration of the gold standard in 1925. The depression following the crisis of 1929 was severe, though the effect on wholesale prices was somewhat offset by the abandonment of the gold basis in 1931. By 1938 wholesale prices in general were little more than 5% above the level of 1913.

There were differences of great significance between the movements of wholesale prices of different groups of commodities, and between wholesale prices on the one hand and retail prices

FIG. 2.—WHOLESALE PRICES AND WHEAT PRICES, UNITED KINGDOM (1913 = 100)

of comparable commodities on the other. The broad comparisons of greatest interest are those between the prices of foodstuffs and the prices of textiles and clothing. In a period of booms, depressions, and wars from 1880 to 1938 there is one broad conclusion which stands out—foodstuffs tended to become relatively cheaper, and textiles and clothing relatively dearer. Moreover, this divergence was greater in retail prices than in wholesale prices. Retail and wholesale prices of food (and also of textiles and clothing) marched together quite closely up to 1914, but, in the general decline of prices between 1924 and 1938, wholesale prices fell more rapidly than retail. The increased margin between wholesale and retail prices arose, at least in part, because of the greater importance of distributive and marketing services. In 1938 wholesale prices of textile materials were rather below the level of 1914 but in the same period clothing prices at retail had more than doubled. There were similar, though less pronounced, differentials for wholesale and retail prices of foodstuffs and fuels.

There were rapid increases in prices during the first three years of World War II, amounting to more than 50% at wholesale and nearly 40% at retail by the end of 1942. Price controls then became effective and prices were generally only 5–10% higher at the close of the war in 1945 than in 1942. In comparison with World War I, price controls operated more quickly and efficiently, and there was no repetition after 1945 of the postwar crisis of 1920.

An important feature of price control, during both the late war years and the immediate postwar period, was the widespread use of subsidies paid to farmers or other producers as a means of keeping down prices. Though not by any means confined to foodstuffs, subsidies were particularly effective in restraining the advance of food prices. For a wide range of raw and processed foodstuffs it was estimated that, whereas retail food prices in 1948 were actually only about 50% above those of 1938, they would have been at double the 1938 level in the absence of subsidies.

From about 1948 until the middle of the 1950s the structure of price control was progressively dismantled; the cushion which had previously absorbed much of the pressure on prices was gradually withdrawn. The play of the various factors influencing prices thus became apparent. The devaluation of sterling in 1949 was

followed immediately by rises in the sterling prices of many imported commodities and a little later by increases in domestic prices at wholesale and at retail. From 1948 world prices of basic foods and materials started to fall but the decline was interrupted by the Korean War of 1950–53, which caused worldwide shortages of foodstuffs and raw materials and hence a rapid and fairly general rise in prices. The opposing influences were almost exactly in balance in 1953–54, a period of relatively stable prices in the United Kingdom. By that time retail prices were on average more than 50% higher than at the end of World War II.

The course of prices from 1954 must be interpreted in terms of the contrast between inflationary domestic pressures and the variable movements in prices of imported foods and materials. The able movements in prices of imported foods and materials. The period of almost steady prices in 1953–54 was followed by a similar but longer period of relatively stable prices in 1958–60. In both cases the rise in the domestic element in costs, typified by wage rates, was little greater than could be offset by falling prices of imports. When these conditions did not obtain, either because of rising import prices or because of greater inflationary pressures, prices at both wholesale and retail advanced rapidly on a wide front. Thus retail prices rose by 4% annually between 1954 and 1958, and the rise was resumed in the early 1960s.

OTHER COUNTRIES

The course of prices in various countries can only be compared after reference to the rates of exchange between national currencies. A suitable standard of comparison is the course of prices in the United States, and the rates of exchange required are then the rates between various national currencies and the U.S. dollar.

As an illustration of the relevance of rates of exchange, prices in France, expressed in terms of the French franc and related to 1913 as a base year, should be considered. At parity in 1913 the French franc was equivalent to 19.3 U.S. cents. The rate of exchange varied after World War I before settling down, in 1927, at the devalued rate of 3.92 cents per franc. Later, on the revaluation of the dollar, the franc appreciated and the rate of exchange in 1934–35 was 6.60 cents per franc. The index number of wholesale prices in the United States varied as follows: 1913

100; 1929, 137; 1935, 115. If wholesale prices in France had followed the same course, except that they were denominated in French francs instead of U.S. dollars, then the index figure in 1929 would have been nearly five times as great as that for the United States (19.3 divided by 3.92) and in 1935 nearly three times as great (19.3 divided by 6.60). Wholesale price index numbers for France would then have been: 1913, 100; 1929, 675; 1935, 340. The recorded levels of wholesale prices in France (in round figures) were: 1913, 100; 1929, 630; 1935, 340.

There are many factors, such as changes in freight rates, domestic costs, and taxes or subsidies, that operate to make domestic prices diverge from world or import prices. In most important countries, however, wholesale prices are in fact largely determined by world prices, and particularly by prices in the United States, at least during periods of stable rates of exchange. The correspondence between French wholesale prices and U.S. wholesale prices expressed in francs at the current rate of exchange was close in 1929 and 1935, each year being related to 1913.

In the period between World Wars I and II the pound sterling diverged little from parity with the U.S. dollar, except during the period before the restoration of the gold standard in the United Kingdom in 1925, and again briefly about 1932 between the suspension of the gold standard by the United Kingdom and that by the United States. Thus the general movements of prices (e.g., a comparison of prices in 1929 or 1938 with those of 1913) are broadly comparable in the United Kingdom and the United States without modification for changes in the sterling-dollar exchange rates. Similar straightforward comparisons can be made in the case of other countries, such as Canada, South Africa, Denmark, and Sweden, whose currencies were more or less closely related to the U.S. dollar or sterling.

In some countries, however, there were limited depreciations or appreciations of the national currencies in terms of sterling and the U.S. dollar. Australia depreciated the Australian pound in terms of sterling in 1930-31. In any comparison of periods before and after 1930-31, therefore, prices in Australia will be found to have risen more than corresponding prices in the United Kingdom. On the other hand, the Netherlands and Switzerland did not follow the United States off the gold standard in 1933, and, when their currencies were devalued in 1936, the depreciation was less than in the case of the U.S. dollar. After 1933 the Netherlands and Switzerland had currencies which were appreciated relative to sterling and the U.S. dollar, and their price levels were correspondingly lower. There were still other countries in which inflation following World War I proceeded much further than elsewhere. The interwar years in such countries—France and Italy being among the more important—were characterized by periods of instability followed by currency reforms and periods of greater stability. The exchange rate in terms of the U.S. dollar was alternately stable and unstable, but the currency was always much depreciated compared with the rate in 1913. Price fluctuations were similar to those in the United Kingdom and United States but always around much higher levels (as compared with 1913).

There was a general fall in wholesale prices from a peak in 1920, steep at first and then more gradual. In most countries the fall continued slowly until 1929, though there was a subsidiary rise in prices around 1924, followed by a fall in 1926-27. This was, in fact, the broad pattern set by the movement of prices in the United Kingdom and the United States. The closeness of correspondence of price movements was greater for countries on the gold standard and these included, by 1925, the United Kingdom, the British dominions, Sweden, the Netherlands, and Switzerland, in addition to the United States. There were some important deviations from the general pattern. In France and Italy, in particular, depreciation of the currency relative to sterling and the U.S. dollar was resumed in 1922 and continued in the following years; the French franc and Italian lira were not stabilized until 1927-28. The fall in wholesale prices in France and Italy was halted in 1922, and prices then rose rapidly in France, and more moderately in Italy, until 1926, in which year the price level was above that reached immediately after the war. In Japan prices remained high during the whole period from 1921 to 1925

and only began to fall with the stabilization of the currency in 1926.

After the U.S. stock market crash late in 1929, wholesale prices declined everywhere, following to a greater or less extent the rapid fall in prices in the United States. In both the United Kingdom and the United States wholesale prices fell to a low point in 1932-33 when their level was not quite 70% of the 1929 level. The effect of the world-wide depression on prices in other countries was varied but three broad groupings can be distinguished.

In one group are countries which devalued their currencies about the same time as the United Kingdom in 1931. Some of them (e.g., Sweden and Australia) devalued to a greater extent and their currencies remained depreciated in terms of the U.S. dollar, not only during 1931-33, but also after the U.S. devaluation in 1933. This depreciation of national currencies offset to some extent the fall in world prices and, though the low point of wholesale prices was still reached in 1932-33, the level was 75-80% of that in 1929 rather than 70% or less. Japan followed much the same course; but wholesale prices had already fallen to 70% of the 1929 level by 1931 (before devaluation) and then recovered immediately.

In a second group of countries, including Spain, Argentina, and Peru, the national currencies were depreciated in terms of the U.S. dollar almost continuously from 1929 to 1932-33. Thus the offset to the fall in world prices was greater, though the depreciation was in no case quite sufficient to prevent wholesale prices from falling. Low points in the level of wholesale prices were reached, in 1932-33, at about 90-95% of the 1929 figures.

The last group of countries comprises those which did not devalue their currencies with the United Kingdom and the United States during 1931-33. Devaluation was postponed, generally until 1936. The Netherlands, France, Switzerland, and (despite some differences) Italy belong to this group. The governing fact here is that national currencies appreciated in terms of sterling from 1931 and in terms of the U.S. dollar from 1933. Thus the fall in world prices was amplified in translation into wholesale prices in national units. The fall in wholesale prices was greater and more protracted than in the United Kingdom and the United States. Low points were reached generally about 1935 and at levels between about 55% and 65% of 1929.

The recovery in prices from the bottom of the depression was almost as rapid as the preceding fall and in most countries it had come to an end by 1937. In that year wholesale prices in the United Kingdom and the United States stood about 20% above the level of 1913 and a little below the 1929 figures. In some countries, like the Netherlands and Switzerland, whose currencies appreciated in relation to sterling and the U.S. dollar in the 1930s, the 1937 level of wholesale prices was lower—a little above the 1913 level but 20-25% below 1929. On the other hand, in countries like Spain, Argentina, and Peru where the national currency continued to depreciate in the late 1930s, wholesale prices in 1937 stood higher, often at levels about double that of 1913 and well above 1929. The price situation in France, and to a lesser extent in Italy, was exceptional in the years immediately before World War II. As in the Netherlands and Switzerland, the rise in prices began late because of the postponed devaluations of currency. But in France and Italy the devaluation of the currency was much more drastic and the price-rise from 1935 was rapid and also continued beyond 1937. By 1939 the level of wholesale prices was above that of 1929, but the process of adjustment was not complete and prices would probably have risen further even if war had not intervened.

Early in World War II most currencies were depreciated and after the war there were further adjustments (mostly downward) in relation to the U.S. dollar. The position in 1948 was that a small group of countries, including Canada, Sweden, and Switzerland, had maintained their currencies at, or restored them to, at least their 1913 par values in terms of the U.S. dollar. Another group, including the Netherlands and Denmark as well as the countries of the sterling area, had devalued moderately in relation to 1913. The difference was larger in Spain and many countries of Latin America, following long periods of almost continuous de-

preciation in terms of the dollar. The most drastic devaluations of all were in the French franc and Italian lira, occurring for the most part after the war.

Prices rose sharply during the war and early postwar years, the relative levels from one country to another being largely dependent on currency adjustments. By 1948 wholesale prices in the United States were less than double those in 1937. In the United Kingdom the change was somewhat greater, as it was in the British dominions, Denmark, Sweden, and Switzerland, though with some variations; for example, the price increase compared with 1937 in Australia was relatively small and in Switzerland relatively large. In the Netherlands the price level in 1948 was higher, about two and one-half times the 1937 figure, following a rapid rise after liberation of the country. In Spain, and in some Latin American countries for which figures were available, wholesale prices in 1948 were between three and four times the level of 1937, as were prices in Egypt and India. The most striking effects of inflation and currency devaluation are to be seen in price changes in France and Italy. French wholesale prices in 1945 were already more than 4 times those of 1937, but in 1948 they were about 20 times the 1937 figure and still rising. It was not until 1949 that prices in France were brought under control. The inflation was even more rapid in Italy, particularly between 1944 and 1947, and wholesale prices in lire reached a level nearly 60 times that of 1937, before a greater degree of stability was attained in 1948-49.

The countries of the sterling area, following the lead of the United Kingdom, devalued their currencies in terms of the U.S. dollar in September 1949. The currencies of most countries in western Europe were devalued at the same time, although not all to the same extent as sterling. Wholesale prices in these countries rose immediately, reversing a tendency toward lower prices which had become evident throughout the world earlier in 1949.

This downward trend in wholesale prices was generally interrupted by the sharp rise in prices of basic commodities in 1950-51 occasioned by the Korean War. Prices settled down once more between 1952 and 1954 but subsequently there was a quite general upward movement, fairly rapid at first but more uncertain and less widespread after 1957. Where prices did rise at all rapidly in the years around 1960 it was because of further currency depreciations, as in some Latin American countries and in France.

Even when allowance is made for exchange rates, there is much less correspondence between prices at retail in different countries than at wholesale. Many retail prices depend little on world prices of commodities, and some are completely insulated against price changes outside the country concerned. Index numbers of retail prices generally relate to the whole budget of an average working-class family, including rents and other services, and the governing factors are domestic costs, taxation, and subsidies. Nevertheless, a general pattern does emerge. By 1924 retail prices were generally higher relative to 1913-14 than those at wholesale, and the difference was increased during the interwar period. On the other hand, retail prices generally rose less between 1937-39 and 1948 than wholesale prices, largely as a result of price controls and of the subsidies placed on foodstuffs and other commodities purchased by working-class households. In many countries, where wholesale prices in 1948 were about double those in 1937, retail prices had increased by only 50-80% in the same period. This differential was diminished in the years after 1948, as price controls were relaxed and subsidies reduced. There was a general upward movement in retail prices between 1948 and the early 1960s but by no means at a constant rate. There were three short periods of relative price stability in most countries: in 1949-50, in 1953-54, and again in 1958-60.

International comparisons of the purchasing power of national currencies are peculiarly difficult to make. The level of retail prices in one country needs to be compared, with allowance for the exchange rate, with the level of retail prices in another country; it is not sufficient to compare the movements over time in one country with movements in another country. The most complete calculations are those made first by Colin Clark and later by M. Gilbert and I. B. Kravis (see *Bibliography*). (R. G. D. A.)

PRICHARD, HAROLD ARTHUR (1871-1947), a leading member of the Oxford "intuitionist" school of moral philosophers, was born on Oct. 30, 1871, at Willesdon, London. He spent most of his life teaching at Oxford, where he was fellow of Hertford College from 1895 to 1898 and of Trinity College from 1898 to 1924, and White's professor of moral philosophy from 1928 to 1937. He died in Oxford on Dec. 29, 1947.

Prichard held that the notion of duty or "ought" is ultimate and irreducible. We become aware of this notion by reflecting on instances of it; in particular circumstances we know directly and immediately, by intuition, that a particular action is our duty, regardless of proof or argument. Moreover, "good" and "ought" are two distinct and mutually irreducible concepts; no proposition about the first can entail a conclusion about the second. Nor can our particular duties be deduced from some more general rule of duty; on the contrary, the ordinary moral rules are themselves generalizations of what we see to be our duty in particular cases.

He also maintained that the rightness of an action does not depend in any way upon its motive; if this precept seems paradoxical, it is because we are liable to confuse motive with intention. With regard to the experience of conflicting obligations, he held that different obligations have different degrees of stringency and that in a particular case we can see which of two conflicting obligations is the more stringent. To account for cases of disagreement about duty, he contended that the capacity of direct moral apprehension may be more fully developed in one man than in another. In his last years Prichard came to think that duty depends not upon the situation as it actually is, but upon what a person believes the situation to be. He also devoted much attention to the concept of promising and concluded that "I promise to do so and so" is not a statement conveying true or false information but that the utterance of these words itself constitutes the act of promising. (See also *ETHICS, HISTORY OF: Modern Ethics*.)

Prichard's theory of knowledge was a development of the "realistic" views of Cook Wilson. Knowing, he held, is something ultimate and *sui generis*, which differs in kind from any sort of belief or opinion; it is, as it were, the direct confrontation of mind and reality. But he eventually came to be dissatisfied with the "realistic" theory of sense perception. Instead he held that sense perception is a kind of illusion and that what is called seeing a chair consists of two distinct factors: (1) seeing a colour, whose *esse* is *percipi*, as Berkeley had said; and (2) mistaking this colour for a body of a certain sort. On this view, the material world cannot be known at all, in Prichard's strict sense of the word "know." Nevertheless, by means of a complicated argument from perceptions to their causes, he thought we could find good grounds for believing that material objects exist and for believing many detailed propositions about them.

For his arguments see *Kant's Theory of Knowledge* (1900); *Duty and Interest* (1928), *Moral Obligation* (1949), and *Knowledge and Perception* (1950), the latter two edited by Sir W. D. Ross.

See E. F. Carritt, "Professor H. A. Prichard: Personal Recollections," *Mind* (1948); H. H. Price's memorial notice in the *Proceedings of the British Academy* (1947). (H. H. P.)

PRICHARD, JAMES COWLES (1786–1848), British physician and ethnologist who early assigned all mankind to a single species, was born on Feb. 11, 1786, at Ross, Herefordshire. Prichard also was responsible for the concept of moral insanity (psychopathic personality) as a distinct disease. He received his early education at Bristol, and early acquired knowledge of European and Oriental languages. After attending St. Thomas's Hospital, London, he went to Edinburgh, where he took his M.D. in 1808. Later he spent some time at Cambridge and at Oxford, but in 1810 settled in Bristol. He was appointed physician to St. Peter's Hospital in 1811 and to the Bristol Infirmary in 1814.

His *Researches as to the Physical History of Man* (1813) was expanded into a five-volume work (1836–47). In 1843 appeared his classic *Natural History of Man*, in which he concluded that there was but a single human species. He was also deeply interested in Egyptology and in 1819 traced the early connection between the Hindus and the Egyptians and published a hieroglyphic alphabet. His *Eastern Origin of the Celtic Nations* (1831) established the place of Celtic languages as a branch of Indo-European. Prichard was elected a fellow of the Royal Society in 1827, and at the time of his death was president of the Ethnological Society. In 1845, on being made a commissioner in lunacy, he moved to London, where he died on Dec. 23, 1848. (W. J. Br.; X.)

PRICKLY ASH (*Zanthoxylum americanum*), a North American shrub or small tree of the rue family (Rutaceae), called also a toothache tree because chewing the leaves, fruits, or bark was once popular as a remedy for toothache. It is found in woods and thickets from southeastern Canada to the Plains states and southward into Virginia and Oklahoma. While usually a shrub it sometimes attains a height of 25 ft. and a trunk diameter of 6 in. It bears alternate, pinnate leaves composed of 5 to 11 ovate, dark-green, somewhat pointed leaflets, with the twigs and leafstalks usually prickly; bruised leaves exude a lemony odour. The small greenish flowers, which appear before the leaves in early spring, are borne in short clusters along the twig; the fruit is a black ellipsoid capsule about $\frac{1}{2}$ in. long, containing one or two seeds.

The similar but larger Hercules'-club, or southern prickly ash (*Z. clavaherculis*), known also as sea ash and pepperwood, occurs along streams from southern Virginia to Florida west to Kansas and Texas. *Aralia spinosa*, of the ginseng family, a spiny shrub or small tree, is also known as prickly ash (see ARALIA).

PRIDE, THOMAS (d. 1658), English parliamentary soldier during the Civil War, is chiefly remembered for his expulsion of members of Parliament from the House of Commons in 1648, known as Pride's Purge. His early life is obscure. Entering the parliamentary army as a captain, he was a major in 1644 under the earl of Essex and was appointed lieutenant colonel of a regiment of foot in 1645. He commanded the regiment at Naseby (June 14, 1645) and at Bristol (September 1645); during the second phase of the Civil War he served with Oliver Cromwell in Wales and fought at Preston (August 1648). In December he took part in the army's occupation of London which was the first step toward bringing Charles I to trial. Under orders from the army council, on Dec. 6, 1648, Pride took his stand at the entrance to the House of Commons and caused the arrest or exclusion of about 140 Presbyterian members. In January 1649 he was one of the commissioners appointed by the remaining Rump Parliament to try the king and he signed the death warrant. He commanded a brigade under Cromwell at Dunbar (Sept. 3, 1650) and fought at Worcester (Sept. 3, 1651). In 1652 he bought the Great Park and Worcester House which were part of the former royal estate of Nonsuch in Surrey. He was knighted by Cromwell in January 1656.

Though a member of the Parliament of 1656, Pride took little part in politics. After the passing of the Humble Petition and Advice (March 1657) he opposed the proposal to make Cromwell king, but accepted a place in the new House of Lords. He died at Worcester House, Surrey, on Oct. 23, 1658. After the Restoration in 1660, the Commons voted that his body should be exhumed and suspended on the gallows at Tyburn, but there is no evidence that this sentence was carried out.

PRIENE (modern SAMŞUN KALE), an ancient city of Ionia on the foothills of Mycale about 6 mi. (10 km.) N of the Maeander (Buyuk Menderes) River, now about 10 mi. inland. According to Strabo, it was founded by Ionians and Boeotians. On its territory was the Panionion, the central shrine of Ionia. Captured by Ardys of Lydia, it enjoyed some prosperity in the earlier 6th century B.C., the period of its "sage," Bias (q.v.). Cyrus captured it (c. 545), but it sent 12 ships to join the Ionian rebels at Lade (c. 494). By 440 it had sunk to being a mere bone of contention between Samos and Miletus. About 350 B.C. it was refounded on the present site, perhaps with outside help. The motive of the refoundation, like the earlier site of the city, remains unknown. The main temple, of Athena Polias, was sufficiently advanced in 334 for Alexander the Great to put his name to it; his dedication stone is now in the British Museum. The whole city seems built to one master plan, and was significantly modified only once—in the later 2nd century B.C. It is tempting to connect this modification with Orophernes, the 2nd-century pretender to the throne of Cappadocia; Priene became his base and he is known to have restored the temple of Athena Polias. After this the little city (about 4,000 inhabitants) led a quiet life until the 13th century A.D., when it was slowly abandoned. It has now been largely uncovered, first by the Society of Dilettanti, later by the German Institute.

Its remains, which lie on successive terraces between the steep north hill, falsely called the "acropolis," and the plain, present one of the most beautiful examples of Greek town planning. The town wall is 7 ft. thick, with square towers at intervals. The main coastal road traversed Priene from east to west. So all three gates are in the east and west walls, the more southerly of the two east gates giving on to a spring. In the grid plan of the town there are six main streets, about 20 ft. (6 m.) wide, running east and west, and 15 streets, about 10 ft. wide, crossing at right angles, all being evenly spaced; and it was thus divided into about 80 blocks or *insulae*. The normal *insula* was about 150 by 110 ft. (46 by 34 m.). The theatre, the gymnasium, and the agora are the only buildings which really overrun the *insulae*. About 50 *insulae* are devoted to private houses. While the better-class *insulae* had four houses apiece, most were far more subdivided. In and near the agora are Doric stoas, fronting the shops. The hexastyle peripteral temple of Athena Polias is on a commanding knoll which overlooks most of the city; it was by Pythius, perhaps the architect of the Mausoleum. It is the classic example of the pure Ionian style. The great altar to its east, with carved standing female figures, is assigned by A. von Gerkan to Orophernes and to Pergamene artists. But its style seems 4th century.

The agora, originally an open space the size of two *insulae*, was later extended at its northeast corner, at the same time that the whole north stoa was rebuilt. The order (Hellenistic "mixed Doric") dates these alterations to the 2nd century B.C. An arched gate, a simple archivolt in design, marked the new east limit of the agora; while behind the rebuilt north stoa was added an assembly hall (*ekklesiasterion*), remarkable for the large arched entrance in its south wall and for the neatness of its auditorium. These arches at Priene are among the earliest in classical architecture to be used consciously for effect. East of the main agora was the early Hellenistic temple of Asclepius, west of it a small separate agora. The theatre is famous for its well-preserved stage buildings, the south gymnasium for yet further instances of decorative arches.

The private houses of Priene, like those of Olynthus and Delos, have each a large room with verandah, facing south across an open yard. But, being smaller, they have to be more oblong in plan.

PRIESTHOOD. The English word priest is the contracted form of presbyter (Greek *presbyteros*, "elder"), also contracted in the form "prester," as in Prester John. The Greek word referred to an office in the early Christian Church already mentioned

in the New Testament. English versions of the Bible, however, render *presbyteros* by "elder," a word whose connotation is very different from the meanings normally associated, in current usage, with priestly office and function, reserving the words priest and priesthood for translating the more specifically sacerdotal terminology (Greek *hierēus*, *hierateuma*; Latin *sacerdos*, *sacerdotium*) of pre-Christian religions. Hence the etymology of the word priest (and its equivalents in many other European languages) is of no relevance for an understanding of the history, nature, and function of the office it is generally understood to refer to.

Any discussion of priesthood in general, however, assumes that certain types of religious ministry are found in most civilizations, that in spite of their diversity these offices and functions are specific and similar enough to justify comparison, and that the terms indicating them can—with due caution—be considered as analogous or at least comparable. There are, of course, no complete equivalences. Usages and technical designations are not uniform, and not every name covers the whole phenomenon intended. There are transitional forms and many instances of overlapping terms and functions. More precise definitions generally achieve their precision at the price of either excessive concentration on the history and terminology of particular religions and civilizations (e.g., biblical priesthood) or arbitrary emphasis on specific characteristics. Nevertheless, a general phenomenology of priesthood, though necessarily of limited validity, is both possible and legitimate.

This article will deal with priesthood in general and, in view of its importance in Western history, with biblical and Christian priesthood. For priesthood in other religions the reader is referred to the respective entries.

Priestly Functions.—In a very wide sense the adverb "priestly" is applied to any function or activity of a religious, and more particularly of a cultic, character in which certain persons act on behalf of others (individuals, smaller groups, or the community as a whole) vis à vis the supernatural powers, (e.g., gods or ancestor-spirits). In many societies certain forms of social organization (the family, clan, etc.) have a sacral character; hence a priestly quality often attaches to the head of the group (chieftain, king, head of the household, etc.) by virtue of the sacerdotal functions he is required to perform. On the other hand, most civilizations also exhibit a definite tendency toward cultic specialization, and it has, therefore, been suggested that the term priest should be limited to the holder of such special office.

Unlike the Roman *paterfamilias*, for example, who also performed priestly or semipriestly tasks, the full-fledged priest, as a religious functionary and cultic specialist, is distinct from the *laos*, the ordinary people or "laymen," who require his services and mediation. Specialization, in its turn, leads to social differentiation and to the establishment of a "clergy"—that is, of a priestly class or caste. Obviously such specialization and differentiation could not arise until mankind had sufficiently progressed to be able to exempt some individuals from the common toil for subsistence and to provide for their needs in exchange for their ritual contribution to the welfare of society. Where such institutionalized division of labour does not exist, as in many primitive societies (and probably also with early man), suitably gifted or knowledgeable persons will perform priestly duties in addition to their ordinary social activities.

There are many types of religious functionaries, specialists, sacred persons, and wielders of religious authority, and the corresponding technical vocabulary is accordingly varied. Sociologists of religion distinguish between the types of founder, reformer, prophet, seer, diviner, teacher, saint, and priest as distinct forms of religious authority. Even when restricting discussion to more specifically cultic functionaries, such diverse names as fetish priest, witch doctor, medicine man, diviner, magician, shaman, priest, etc., are found. Frequently functions overlap. Roman Catholic theologians are generally priests; in India only Brahmans were traditionally permitted to study and recite the Vedas; and divination is frequently a priestly function (as, for example, in the case of the college of augurs and the *quindecimviri sacris faciundis* at Rome). The latter institution also shows how sacerdotal media-

tion operates in two directions: the priest not only does "those things which are ordained to be done toward the gods" (Aristotle, *Politics*, vi, 8) but also acts as the representative or mouthpiece of the godhead vis à vis the community, as in interpreting oracles or in administering sacraments.

The wide spectrum of sacerdotal functions is illustrated by the fact that occasionally the same philological root gives rise to less inclusive and more differentiated meanings in different cultures: the Canaanite word which meant priest in Ugaritic (*khn*) and in Hebrew (*kohen*) signified "inspired soothsayer" (*kahin*) among the ancient Arabs (see *PROPHET*). In many cultures further differentiation occurs within the priestly order and is attested by the existence of different names for different classes of priests as well as by specialized ministries, such as special priesthoods for particular gods (e.g., the Roman *flamines*; see *FLAMEN*) or for particular functions (e.g., the Roman pontifices; see *PONTIFEX*).

Generally speaking, the term priest is best applied to religious functionaries whose activity is concerned less with the purely mechanical techniques of magic than with the right performance of the ritual acts required by the divine powers and supernatural beings recognized by the group in which the priest exercises his office. As sacrifice (*q.v.*) is one of the most prominent features of man's ritual relations with the world of gods and spirits, it has come to be associated with priesthood as one of its chief functions; e.g., medieval Catholicism owed much of its doctrine of the priesthood to the connection of the latter with the Eucharist conceived as a propitiatory sacrifice.

The specialists leading the group rituals conform most closely to the "ideal" phenomenological concept of priesthood. The ancient Inca, Maya, and Aztec distinguished between priests responsible for the cult of the great national gods and such ritual experts as were resorted to for more specific and individual needs such as divination or curing. Similarly many African societies differentiated between priests responsible for the worship of the tribal ancestors, on the one hand, and witch doctors, etc., on the other.

Priesthood, in its fully developed form, generally implies large societies with centralized authority, a fairly elaborate culture, and the existence of an organized cult with fixed rituals and well-formulated doctrines. However, it would be a mistake to assume that every highly developed religion of necessity possesses a priesthood. Islam is perhaps the best example of a religion without priests, religious authority being defined in other than sacerdotal terms. Buddhist doctrine has no room for sacrificial ritual and priestly intervention, although certain sacrificial aspects are implicit in the Bodhisattva ideal. Yet in actual practice—especially in Mahayana, but to some extent even in Theravada Buddhism—there is little to distinguish a *bhikkhu*, or monk, from a priest. Theravada has never produced a rigid ecclesiastical machinery and hierarchy, but many Mahayana sects have progressed far on the road of hierarchical sacerdotalism. Tibetan Buddhism in particular has produced a type of priesthood whose ritual techniques are indistinguishable from magic.

Many primitive societies exhibit patterns of "priesthood of all believers"; i.e., of all members of the group. Thus the Pueblo Indians in the United States Southwest were organized in religious fraternities, and the highly formalized and elaborate rituals necessary to ensure fertility and the general welfare were performed by these groups and not by priestly functionaries.

Even where individual priests exist, their function is not necessarily one of mediation between men and gods, since prayer, sacrifice, and the administering of oracles do not everywhere require special sacerdotal practitioners. Among the Nuer of the Nileotic Sudan the leopard-skin priest, according to E. E. Evans-Pritchard, "has a central position in the social structure rather than in religious thought." Two social groups may become so violently opposed (e.g., as a result of homicide) that only a person unaffiliated by lineage attachment to either party can effectively act in the situation and offer sacrifice and administer oaths. Since he has no political authority whatever, it is only in virtue of the sacrosanct quality of his person that the leopard-skin priest can carry out his function—somewhat like a medieval ecclesiastic arranging for

a truce of God, precisely because (in theory at least) he stands outside the warring factions.

Popular and State Priesthoods.—The origins of priesthood are largely a matter of conjecture. In some primitive societies, and possibly with early man too, ritual functions (e.g., fertility or hunting magic) are simply performed by such individuals as have shown in practice that they possess more supernatural "power" (*mana*; *q.v.*) than others—that is, are more successful in curing the sick, controlling the weather, charming deer in the hunting season, detecting sorcerers, etc. Men are distinguished from one another by a variety of gifts, and some, it would appear, possess the gift of mediating between the human and the spirit worlds to a greater degree than others.

As ritual traditions and practices increased in number and complexity, and society evolved forms of specialized division of labour, ritual practitioners arose and were resorted to. Eventually they organized themselves into priesthoods. The Bible still presents Noah, Abraham, Jacob, and other patriarchs as offering sacrifice, but later Old Testament legislation prohibits any sacrifice except that offered in the Temple of the Lord through the priests, "the sons of Aaron" (see below, *Semitic and Israelite Priesthood*). Nevertheless a distinction should probably be made between popular priesthoods (the ritual specialists of popular religion) on the one hand and official (state) priesthoods on the other.

The latter appear to have arisen as a result of the centralization of authority in the city-states, and they frequently ousted the earlier popular priesthoods or absorbed them into their ranks. The rise of a state priesthood actually means that the sacerdotal function is conceived as an essential aspect of political authority in general and of kingship in particular. The connection of kingship and priesthood is also implied in G. Dumézil's thesis regarding the tripartite structure of the world of the early Indo-Aryan tribes, according to which the three classes of priests, warriors, and peasants correspond to the three basic social and sacral functions of sovereignty, war, and growth. Most modern accounts of ancient Near Eastern kingship emphasize, to a greater or lesser degree, its sacral and priestly character. The king was, in theory and often also in practice, the chief cultic functionary, though normally his ritual duties were delegated to the priests acting in his behalf. Whereas the popular priesthood is often associated with popular and local shrines, the state priesthood is connected with the temple, which, in its turn, is closely associated, and possibly originally identical, with the royal palace. Even where in actual practice this link no longer exists, traces of it occasionally remain in the royal titles of the highest priestly functionaries; e.g., the archon (*q.v.*) at Athens and the *rex sacrorum* at Rome. (See further KING; MESSIAH.)

Recruitment and Training of Priests.—Great variety exists in the forms of recruitment and training for the priesthood. Often a priest is simply chosen and appointed by the traditional owners of a cult. Sometimes a young man (or his family) decides on a sacerdotal career and serves an apprenticeship with an elder priest. Others are called to belong to the god by a personal experience (which may be culturally stereotyped), as by "possession" during an ecstatic trance. With many prospective shamans, signs of a vocation are discernible long before the first possession actually takes place—usually after the shaman has vainly tried to resist the call (see SHAMANISM). Sacerdotal appointments, like those of secular magistrates, were often made directly by state authority (as to the Egyptian priesthood during the Old and Middle Kingdoms or to the pontifical colleges of ancient Rome) or subject to its approval.

The sacerdotal office (ownership of a particular cult, the right to serve at a certain shrine or to exercise a specific type of ministry) is frequently inherited, and ritual functionaries tend to form classes in which the priesthood becomes hereditary (as in the New Empire in Egypt). As priestly celibacy is very rare, hereditary priesthood is correspondingly frequent. This can mean that priests must be chosen from certain lineages or that all members of a certain lineage or tribe or caste are *ipso facto* priests. Perhaps the best-known example of a priestly caste is provided by the Brahmins of India (see BRAHMAN), who are gen-

erally described as possessing an almost complete monopoly on religious affairs: blessing, cursing, sacrificing, administering sacraments, reciting the Vedic scriptures, etc. (In reality, however, matters are more complicated, since certain "priestly" functions, as responsibility for rain and growth, seem to have belonged to the sphere of kingship.) Similarly the Magi (*q.v.*) became a hereditary sacerdotal caste whose presence was indispensable at any Iranian religious ceremony and who eventually completely monopolized the Zoroastrian priesthood. Among the ancient Hebrews, the Levites eventually came to function as the priestly tribe. The leopard-skin priests of the Nuer are members of a particular lineage.

In most civilizations the male sex predominates among ritual functionaries, though female shamans and priestesses (the vestal virgins at Rome, for example) are not uncommon.

Whatever the nature of the priestly "power"—whether the *charisma* of office bestowed through ordination (which may be held to confer an indelible character); or a spiritual or magic power acquired by personal experience (vocation, divine possession); or the presence of the sacred life force exhibited in mortal combat (as by the priest of Diana at Lake Nemi); or the participation, by reason of birth, in the power of holiness (as the *brahman* of the Indian Brahmins, and possibly the *maga* of the Iranian Magi)—the exercise of the sacerdotal office generally requires preparation and training, both theoretical (myths, traditional lore, cosmology, law, theology, writing) and practical (ritual, divination, and other techniques). Even in nonliterate societies the system of training priests occasionally reached high levels of complexity (as in Dahomey) and intellectual sophistication (as in Polynesia). In higher civilizations the priesthoods were the depositories of literate learning and the guardians of sacred as well as secular lore, including cosmic-astral knowledge and law. Hence also the judicial functions, both divine justice (e.g., by means of the sacred lot or ordeals) and normal jurisprudence, often exercised by the priesthood.

Priestly Castes and Hierarchies.—The consolidation of priestly castes and classes has important religious, social, and political consequences. The special status of priests is frequently indicated by distinctive dress. Even though they may have to observe special restrictions and taboos, they generally have enjoyed considerable privileges and have claimed (often successfully) immunity from temporal law and duties. Priestly monopoly of ritual and the inevitable corruption resulting from the accumulation of power and prestige more than once has provoked or stimulated antisacerdotal reactions both on theological and on social grounds. Priestly establishments tend to develop doctrines extolling their divine nature and function. Even if the well-nigh incredible pretensions sometimes expressed in Brahmanic literature often reflect wishful thinking rather than social reality, the doctrinal tendency is evident: Brahmins are gods. According to the Roman catechism of 1567 priests are fittingly called not only angels but "gods" because *Dei immortalis vim et nomen apud nos teneant* ("they are the holders, among us, of the power and the might of the immortal God"); and according to the encyclical *Mediator Dei* of Pius XII the priest "*alter est Christus*" *cuius personam gerit* ("is 'another Christ,' whose person he represents").

Priesthoods tend to hierarchical organization, and social, cultural, and intellectual differences among the various classes, sections, or subcastes of a priestly order can be very great. Different rules and requirements may be applied to priests of different type or rank. Certain rituals require that the officiating priest be of a specified status: the ancient Jewish ritual of the Day of Atonement had to be performed by the high priest; Christian confirmation and ordination are conferred by a bishop; the priest officiating at a Parsee initiation must have the degree of *mobad*, conferred on the second investiture. As a class with its own interests, values, and loyalties, priesthood has often shown an inclination to exercise direct or indirect political power, thus giving rise to the problem known in Western history as that of church and state (*sacerdotium and imperium*; see CHURCH AND STATE) and to such diverse forms of relationship as state control, support, or total suppression of the priesthood, caesaropapism, theocracy,

etc. Between the Indian castes of Brahmins and Kshatriyas (the ruling caste) there are indications of an original relationship of both rivalry and complementarity. Even when the priestly hierarchies have made no open bid for seizing direct political control, they often have interfered in political affairs, made and unmade kings, kept armies of their own, and occasionally succeeded in creating a "state within the state" (as, for example, that established during the 21st dynasty in Egypt by the clergy of Amon in Thebes, or the Taoist "papacy" founded by Chang Ling in the 2nd century A.D.). Priestly income consisted of the revenues of the temple at which they served, gifts and sacrificial dues (e.g., tithes), or salaries paid either by the state or by the ecclesiastical organizations.

Semitic and Israelite Priesthood.—The Babylonian and Assyrian priesthoods were associated with an official state cult and organized in specialized priestly guilds (soothsaying, divining, performing the great state rituals); a similar situation probably obtained in the Phoenician and Canaanite city-states. The nomadic and seminomadic Semitic tribes, on the other hand, appear to have had no hierarchical and organized priesthood. There were, of course, local sanctuaries of greater or lesser fame, in the charge of priests, where people would go on pilgrimages or in order to receive an oracle or obtain divine judgment by the sacred lot. Israelite priesthood exhibits the transition from popular to a more fully organized royal priesthood after the establishment of the monarchy by David (10th century B.C.), but its origins and the details of its history are obscure, and reconstruction depends on the interpretation of the literary and other evidence and on the dates ascribed to the various biblical documents.

It appears that Hebrew priesthood derives from at least two sources: the tribe of the Levites (*q.v.*) at some time became the hereditary sacerdotal ministers and zealous sponsors of the Mosaic Yahweh religion, whereas the Aaronides (*see* AARON) were the ancient, pagan priesthood of Israel. The biblical account of the institution of Levitical and Aaronide priesthoods compresses a long history of social and religious development and harmonizes the fierce rivalry that must long have existed between the two groups. No doubt the administering of oracles by sacred lot and the ephod (*q.v.*) was one of the main priestly functions at many local shrines; cf. Gen. 25:22, Judg. 17–18, I Sam. 14, Ex. 21:6 and 22:8–9 (reading, with the Revised Standard Version, "God" for "judge," "judges" in the Authorized Version), Ex. 33:7 ff., I Sam. 22:18–23:12. But apart from oracle reading, Israelite priests seem to have performed none of the functions associated with the priestly office among their neighbours. Neither Leviticus nor Deuteronomy suggests that cures, spells, incantations, funerary cults, ecstatic prophecy, mythological recitations, fertility cults, ritual dramas, or the like formed part of the sacerdotal ministry. The view that any of these rituals existed in ancient Israel assumes that many of the relevant facts were concealed by the biblical record but can be inferred from what is known, or thought to be known, about the cultic institutions of the neighbouring societies. In view of the question-begging argument, the case cannot, as yet, be said to be proved.

The Pentateuch presents the priestly cult as being solely concerned with preserving the sanctuary (*viz.* the "tent of meeting," or tabernacle [*q.v.*], in which the divine presence is thought to be manifest) from ritual defilement. Sacrifice is for purification and atonement. Blessing the people was a marginal rather than a central function (Lev. 9:22; Num. 6:23), though it is the only one which the priests have retained in later Judaism, since the destruction of the Temple (A.D. 70). On the other hand, the priests were in charge of the Torah, Yahweh's laws and statutes (cf. Deut. 33:8; Jer. 2:8) until, in the Second Temple period, this function was assumed by the Pharisaic teachers and rabbis. The priests of the "royal chapel" (*i.e.*, the Temple at Jerusalem), the sons of Zadok appointed by Solomon, gradually gained ascendancy over all other priestly families, especially after the abolition of local sanctuaries and the centralization of worship in Jerusalem.

By the time of the Second Temple (6th century B.C.) the priesthood was considered a hereditary hierarchy officiating by divine

right; its prestige as well as its political and social significance in the life of the nation reached unprecedented heights. Politically the priestly class was associated with the Sadducees rather than with the Pharisaic party (*see* JEWISH SECTS DURING THE SECOND COMMONWEALTH), but sectarian groups accorded a major place to the priesthood as such in their theological system, though emphatically repudiating the "usurpers" who actually held priestly office in Jerusalem during the Hasmonaean and Herodian periods.

The doctrine and institution of priesthood play little part in later Jewish theology. When Christianity began to evolve the notion of a sacerdotal ministry, the Temple was no longer in existence; the church was not guided or influenced by any living Jewish example or institution but by its own understanding of the model of priesthood in the Old Testament.

Christian Priesthood.—New Testament usage does not associate any "priestly" notions with the office of presbyter ("elder"; *see* above) and never applies the term priest (*hiereus*) to Christian ministers. On the other hand, the ministry, and more particularly the sacrifice, of Christ were conceived in high-priestly terms (Heb. 5). The sacrifices and priesthood of the Old Testament were understood as a type or prefiguration of Christ's sacrifice (cf. Rev. 13:8, "the Lamb slain from the foundation of the world") and priesthood (Heb. 5:10), in which they were fulfilled. All Christians, however, were held to share in his high priesthood (cf. Eph. 2:18), and hence the Christian community as a body could be described as a holy or royal "priesthood" (I Pet. 2:5, 9; cf. also Rev. 5:10).

Nevertheless a Christian ministry of the sacerdotal type soon began to emerge, mainly in connection with the Eucharist. By the 3rd century Cyprian (*Epistles* 66) could declare *episcopum in ecclesia esse et ecclesiam in episcopo* ("the bishop is in the church and the church in the bishop"). In fact, the *sacerdotium* was vested primarily in the bishop, but the "presbyters" shared in it and, in his absence, could exercise certain priestly functions acting as his delegates. With the spread of Christianity and the establishment of parish churches, the parish priest became the principal celebrant of the Eucharist, and in this capacity, as well as by hearing confession and granting absolution, he eventually assumed the role of the representative of God to the people rather than the other way round. The development of eucharistic theology resulted in a further emphasis of the priest's supernatural powers and qualities in a manner which went far beyond the Old Testament model which was considered to provide the pattern of both priestly mediation and priestly hierarchy.

The Protestant Reformation rejected the doctrine of the sacrifice of the Mass as well as the conception of a "Levitical" priesthood for that went with it, and consequently substituted "ministers" for "priests." The English Reformers retained the term priest in the Book of Common Prayer, in order to distinguish priests, who can celebrate Holy Communion, from deacons, who are not entitled to do so. Since the 19th century, theology has witnessed a notable revival of sacerdotalism, accompanied, however, by a renewed emphasis of the priesthood, in Christ, of the whole people of God (*see*, for example, the relevant sections in the encyclical *Mediator Dei* of Pius XII).

PRIESTLEY, JOSEPH (1733–1804), a dissenting English clergyman, by avocation a chemist and as such the celebrated discoverer of oxygen. He is equally well known in his native land and in the United States where he spent the last ten years of his life. Born at Fieldhead, near Leeds, on March 13, 1733, the son of strict Calvinists, he was destined for the ministry. Displaying an independent mind, he soon rejected the authority of the established churches and became a dissenting minister at 22, and five

years later a teacher of classics and literature at a private school in Warrington. There he wrote an essay on education and a compilation on eminent men of all ages, which earned him a doctor of laws degree from the University of Edinburgh. This study necessitated frequent trips to several cities, including London, where he met and was befriended by Benjamin Franklin. At the latter's suggestion he wrote a *History of Electricity*, which proved so successful that he was admitted, at the age of 33, to the Royal society.

Following a disagreement with the trustees of Warrington academy he resigned in 1767 and became pastor of Mill Hill chapel, near Leeds. Living next to a brewery, he became interested in the "fixed air" (carbon dioxide) that lay over the liquids in the fermentation vats.

On moving to another location he continued his studies with this gas, which he made by pouring acid on chalk. He dissolved the gas in water and obtained "an exceedingly pleasant sparkling water, resembling Seltzer water." For this application, which was his first contribution to the chemistry of gases, the Royal society awarded him the Copley medal in 1773. About this time Priestley met a fellow sympathizer with the cause of the American colonies, Lord Shelbourne (later marquess of Lansdowne). He became librarian and literary companion to this wealthy nobleman, with enough leisure to indulge in scientific pursuits.

With the aid of a newly acquired burning glass, he obtained on Aug. 1, 1774, a new gas from mercuric oxide that was five or six times as pure as ordinary air. He even foresaw its future uses: "it may be peculiarly salutary for the lungs in certain cases" and thus anticipated its use in oxygen tents. This discovery, which greatly increased his fame, led to a meeting in Paris with Antoine Lavoisier and other noted scientists. Lavoisier at once repeated Priestley's experiments with the new gas, which he named oxygen because of its acid-forming properties. It gave Lavoisier the clue to demolish the phlogiston theory of which, nevertheless, Priestley remained a lifelong adherent. Meanwhile, the theological heresies of Priestley strained the relations with his patron to such extent that he resigned in 1780 to become minister to a dissenting congregation in Birmingham. There Priestley found kindred souls with liberal outlooks in politics and religion who induced him to join the so-called Lunar society (outsiders called it "lunatic") which met on Monday nights nearest to full moon.

In Birmingham, where Priestley spent the happiest decade of his life, he wrote the final two of his six volumes *On Different Kinds of Air*. An abridged edition in three volumes appeared in 1790. Priestley's nontechnical writings, particularly his *History of the Corruptions of Christianity*, his espousal of the cause of the American colonists and later of the French Revolution, and especially his outspoken reply to Edmund Burke's attack on the new regime in France, made him exceedingly unpopular with the public. The smouldering resentment against Priestley and his friends came to a head on the second anniversary of the fall of the Bastille (July 14, 1791). Mob rule existed in Birmingham for three days. Priestley's church, his house and his laboratory were burned and he himself escaped in disguise to Worcester. Later he settled in London, where he spent three unhappy years. On April 7, 1794, he left for America to join his three sons who had already found new homes there. Arriving in New York city in June 1794, he was offered a professorship and a ministry, both of which he declined. He built himself a house and laboratory in the town of Northumberland, Pa., and there he died on Feb. 6, 1804.

JOSEPH PRIESTLEY. PORTRAIT IN CHALK BY ELLEN SHARPLES, ABOUT 1795

Priestley's multiplicity of interests has often been commented upon. Trained as a theologian, he was open-minded, fearless and progressive in matters of religion and politics; in science, to which he came later in life, he was orthodox, timid and as he himself stated "not apt to be very confident" about conclusions from his observations. Even so, he had the attributes of a born investigator: an intense curiosity, a passion for "experimental philosophy" and a native honesty and frankness. He was an ingenious manipulator. Being the first to collect gases over mercury, he discovered, in addition to oxygen, several other gases, including nitrogen, ammonia, nitrogen dioxide, nitrous oxide, hydrogen chloride, and sulfur dioxide. Some of these are highly soluble in water and thus had escaped the attention of contemporary chemists. Another significant contribution to chemistry was Priestley's work on "the purification of air by plants and the influence of light on that process," which provided the stimulus for subsequent studies by Jan Ingenhousz, Jean Senebier and others on respiration and photosynthesis.

See also references under "Priestley, Joseph" in the Index.

BIBLIOGRAPHY.—An excellent account of Priestley's contributions to chemistry is found in J. R. Partington, *A Short History of Chemistry*, 2nd ed. (1948), which contains numerous references. For a popular account of his life and work see B. Jaffe, *Crucibles* (1934), and J. G. Gillam, *The Crucible* (1954); see also R. E. Crook, *A Bibliography of Joseph Priestley, 1733-1804* (1966), which lists 509 titles by Priestley and 127 works relating to him. His work on oxygen has been republished in *The Alembic Club Reprints*, no. 7 (1901) and in H. M. Leicester and H. S. Klickstein, *A Source Book in Chemistry* (1952). A good account of Priestley's relations with Lavoisier was given by R. E. Oesper in *J. Chem. Educ.*, 13:403 (1936).

The centennial of the discovery of oxygen, celebrated by a group of American chemists at Priestley's home in Northumberland, was followed by the founding of the American Chemical society in 1876. The semicentennial meeting of the society led to the issue of a "Priestley Number" of the *J. Chem. Educ.*, 4:145-199 (1927), which contains illustrations and details of his life in America. (H. S. V. K.)

PRIEUR, PIERRE LOUIS (PRIEUR DE LA MARNE) (1756-1827), French revolutionary, was born at Sommesous, in Champagne, on Aug. 1, 1756. Having been a lawyer at Châlons-sur-Marne, he was elected to the Estates-General in 1789. An honest patriot, he spoke for measures against the *émigrés* and for the organization of justice. In the Jacobin Club, of which he was president in June 1791, he supported the incorporation of Avignon into France. Appointed deputy public prosecutor on the criminal tribunal of Paris (November 1791), he subsequently had himself appointed public prosecutor for the *département* of the Marne, which he represented in the Convention. In September 1792, he undertook a mission to F. C. Kellermann's army. On the trial of Louis XVI, he voted for the death sentence without reprieve. A member of the Committee of General Defense, from March 24, 1793, he was entrusted with missions to Orléans and later to the Army of the Cherbourg Coast. A member of the great Committee of Public Safety from July 10, he went to the armies of the North and of the Moselle, and then to Brest (September), to Morbihan, and to the Army of the West, where he contributed to the defeat of the Vendean rebels at Le Mans (December). He was in Loire-Inférieure in January 1794, then at Brest again. Recalled to Paris, he was elected president of the Convention on Oct. 22, 1794, but on May 21, 1795, his arrest was ordered. Escaping, he obtained an amnesty. After this he took no further part in politics and went back to the bar. Going into voluntary exile in Brussels in 1816, he died there, destitute, on May 30, 1827. (MA. Bo.)

PRIEUR-DUVERNOIS, CLAUDE ANTOINE (PRIEUR DE LA CÔTE D'OR) (1763-1832), French revolutionary remembered for his services to national defense and economy, was born at Auxonne in Burgundy on Dec. 22, 1763, the son of a revenue collector of taxes of the Dôle bailliage. A member of the petty nobility, he entered the military engineering school at Mézières and became captain of engineers in 1791. A deputy of the Côte d'Or *département* in the Legislative Assembly and later a member of the Convention, he was sent on a mission to the Army of the Rhine on Aug. 10, 1792, and to the Ain and Jura frontiers in October. After the execution of Louis XVI (January 1793), for which he had voted, he was detailed to inspect the Channel ports and afterward the Army of the Cherbourg Coast (April) and was

arrested by the Norman federalists. Released on July 29, he returned to Paris and became a member of the Committee of Public Safety (Aug. 14, 1793). He then concerned himself with the production of war material, with military schools, with mines, and with public works and health, also undertaking missions to the Army of the West (October) and the *département* of the Nord (December). A member of the Committee of Public Instruction, he contributed to the establishment of the metric system of weights and measures. A quiet and conscientious worker, moderate in his views, he was elected to the Council of the Five Hundred (1795) and sat in it until May 1798. He was attached in June 1798 to the Committee of Fortifications. Appointed a brigade commander (1801), he did no more military service, but founded a wallpaper factory. He died at Dijon on Aug. 11, 1832.

PRILEP, a town in the Socialist Republic of Macedonia, southern Yugoslavia, is 116 km. (72 mi.) S of Skopje by road. Pop. (1961) 39,611. There are six medieval churches (the most famous being St. Nikola, 1298) and mosques. The town lies on the railway from Titov Veles to Bitola and Salonika. Its fertile valley gives the best brand of Macedonian tobacco; there is also a marble quarry. The town is well known in the history of the south Slavs as the birthplace and capital of Marko Kraljevic, the hero of south Slav folk songs. In the Balkan Wars of 1912–13 the Serbs successfully stormed the heights of Prilep, reputed to be impregnable. The first Macedonian partisan unit of World War II operated in the Prilep area in 1941, and the partisans liberated the town from the Germans in 1944. (V. Dz.)

PRIM, JUAN (1814–1870), Spanish general and statesman, a leader of the revolution of 1868, was born at Reus, Catalonia, on Dec. 6, 1814. At the beginning of the First Carlist War (1833–39) he enlisted in the forces supporting Isabella II. His courage, and the fact that he had been in action 35 times, raised him to the rank of colonel by 1839. A liberal by conviction, he entered politics and was elected deputy for Tarragona in 1841. The following year he opposed the regent, Baldomero Espartero, and in 1843 led a rising at Reus which led to Espartero's exile. In the same year Gen. Francisco Serrano y Domínguez appointed Prim military governor of Madrid and later, of Barcelona, where he was responsible for the harsh repression of attempted risings and received the titles of conde de Reus and vizconde del Bruch. He soon became an opponent of the moderates and conspired against the prime minister Ramón Narváez. Captured and condemned, he was later pardoned. He traveled to France and to England, and in 1847 was appointed governor of Puerto Rico. There he repressed disturbances by the slaves and put down banditry.

On his return to Madrid he was given command in 1853 of the Spanish commission attached to the Turkish Army fighting the Russians. He was appointed captain general of Granada in 1856. From there he went in 1859 to Melilla, in Morocco, where he suppressed a rising and was given the titles of marqués de Castillejos and marqués de Wad-Ras (1860). He commanded the English, French, and Spanish expedition to Mexico (1861), and obtained from Pres. Benito Juárez the reparations which the allies had demanded (see Mexico). However, he refused to support the French plan to impose the archduke Maximilian of Austria as emperor of Mexico, and returned to Spain. He then associated with the antidynastic sections of the Progressive Party; he was accused of conspiracy and exiled to Oviedo (1864). From then until 1868 he took part in all the *pronunciamientos* and played a principal part in the successful one of September 1868, which deposed Isabella II. He was made minister of war in October in Serrano's government, and when the latter became regent in 1869, Prim headed the government and acted firmly in suppressing disorder. After considerable difficulty he succeeded in getting Amadeo of Savoy accepted as king of Spain, but on Dec. 28, 1870, Prim was attacked by assassins in Madrid and died there on Dec. 30, the day Amadeo arrived in Spain. (R. S. Ll.)

PRIMARY, a meeting or election at which candidates for office are nominated or at which the first steps are taken toward such nomination. Primaries may be informal gatherings or formal

elections held under the same safeguards as final elections. They may be partisan in the sense that participation is limited to persons affiliated with the same party; or nonpartisan, in that nominees are chosen without regard to party affiliation. Partisan primaries may be indirect or direct. In the former, delegates are chosen to nominating conventions which then choose the nominees; in the direct primary the party members choose the nominees and the primary becomes a preliminary election in the electoral process.

Historical Development.—The formalized, legally regulated primary election and the direct primary are peculiar to the United States. The earliest method for nominating candidates was the caucus (*q.v.*) adopted in colonial times for local offices and continued into the 19th century for state and national offices. Nominating conventions, instituted by political parties as a means of doing away with the abuses of the caucus system, eventually became subject to abuses which led first to their regulation and ultimately to their elimination for most offices except president and vice-president (see NATIONAL CONVENTION). Observance of early laws relating to selection of delegates was optional, parties being permitted but not required to conform to their provisions, and the laws were limited to certain areas. After 1890 mandatory regulations of a sweeping character transformed the primary into an election conducted by public officers at public expense. Even before these laws were tested a demand arose for making nominations by the voters directly. The direct primary was used by the Democratic Party in Crawford County, Pa., as early as 1842, but it was not until the 20th century, when the Progressive movement tended to divide both parties, that the system came into general use. In 1903 Wisconsin, under the leadership of Gov. Robert M. La Follette, passed the first mandatory, statewide direct primary law. The movement spread so rapidly that by 1917 all but four states had adopted the direct primary for some or all statewide nominations. After the passage of laws in Utah (1937), New Mexico (1938), Rhode Island (1947), and Connecticut (1955), some form of direct primary was used in all states. Primaries in most states are mandatory and cover nominations to all state and county offices, but optional primaries survive in several Southern states, and Michigan, New York, and Indiana are among the states which use conventions for nominations to some state offices. In most states provisions apply only to parties polling a fixed minimum at the last election.

Beyond this, few generalizations are possible; direct primaries in the states vary widely in detail, and dates of primary elections vary from spring to fall. Various methods are used to place names on the ballot. The simplest is a declaration of candidacy, with or without a filing fee. The more popular method is by petition signed by a certain number of political supporters of the aspirant. In an increasing number of states the primary is preceded by official or unofficial conventions and candidates so designated are listed first on the ballot. Preprimary endorsing conventions are provided by law in Colorado, Connecticut, Idaho, Massachusetts, New Mexico, and Utah. In Rhode Island party committees may endorse candidates and their names appear first on the primary election ballot. On the other hand, California in 1963 prohibited party organizations from officially endorsing candidates and required nominees of unofficial clubs to be labeled "unofficial" on the ballot. In most states an aspirant for nomination may compete only in the primary of the party in which he claims membership, but in a few states it is possible for the candidate to seek the nomination of both parties simultaneously. In California this practice, known as "cross filing," was repealed in 1959.

"Open" and "Closed" Primaries.—Particularly interesting and important are the variations in qualifications for voting in the primary. Some primaries are "open" in the sense that no declaration of party affiliation is required; the voter may participate in the primary of either party and move from one party to another in successive contests. Sometimes, as in Wisconsin, the participant receives the ballots of all parties and may decide which to use in the privacy of the voting booth, whereas in those states following the Minnesota plan a "blanket" ballot is provided in which the names of all candidates are arranged in party columns.

In 1935 Washington adopted a blanket ballot which permitted the voter to cross back and forth between the parties at the same primary; e.g., he might vote for a Republican aspirant for the gubernatorial nomination and at the same time express a choice for a Democrat for the nomination for United States senator. The "closed" primary, used in all but seven states by 1964, limits participation in the primary to party members. Voters are required to enroll as members of a party at the time of registration, to state their party choice at the polling place, or to swear that they meet a specified test of party membership if their right to participate in the primary is challenged. The usual tests are support of the party's candidates at the last general election or the intention to support the candidates of that party at the next general election.

The merits of open and closed primaries have been widely debated. It is argued that the open primary permits participation by independents who are unwilling to declare a party affiliation and that it prevents intimidation of voters. Its opponents say that it destroys party responsibility by permitting those who have no continuing allegiance to the party to control its nominees, and that it permits members of one party to "raid" the primaries of the other party.

Primaries were for many years regarded by the courts as being outside the power of Congress to regulate. Federal corrupt practices acts, for example, were held not to apply to primaries but only to final elections. In Southern states Negroes were barred from voting in Democratic primaries, which were the only elections that really mattered, and the courts held that such action by the Democratic state organizations was not unconstitutional. In the 1940s this interpretation was set aside in several U.S. Supreme Court decisions to the effect that primaries are integral parts of the electoral process, that political parties are not private clubs but state agencies, and that the primaries in which candidates for federal office are chosen are subject to federal regulation.

Other Aspects.—In most states the candidate polling the highest number of votes becomes the nominee, but by the early 1960s most Southern states, in which Democratic nomination was equivalent to election, required a second or "runoff" primary if no candidate received a majority of the votes in the first contest. Preferential voting (i.e., indication of a first, second, and third choice), tried by several states, had been abandoned by all of them.

Studies made in the 1950s and 1960s tended to support the hypothesis that the primaries had altered the character of political competition, at least in the case of nominations for state legislative posts. Even in two-party areas the effective choice had tended to be transferred to the primaries of the majority party, and the vitality of the minority party was weakened.

Attempts have been made to extend the idea of direct nominations to the presidency of the United States. By election of delegates to the nominating conventions, and by preference votes for president, or both, some states have attempted to bring the national conventions within the control of the party membership. The first mandatory presidential primary law was adopted by Wisconsin in 1905, and by 1916 laws varying widely in type and effectiveness were in operation in 24 states. After that the movement lost ground, and in 1964 mandatory laws were in effect in only 16 states and the District of Columbia. Nevertheless, studies published in the 1960s suggested that primary contests affected the action of national nominating conventions and there was a revival of interest in proposals for mandatory national presidential primaries.

Nonpartisan primaries have been widely used for judicial and local offices in the United States and have been extended to members of the state legislature in Minnesota and Nebraska. In reality a double election system in which party labels play no part, nonpartisan elections, and primaries were introduced in an attempt to remove these offices from influence by national party politics. Although nonpartisan in form, they frequently become partisan in fact.

The closest parallel to the U.S. primary has been the "preselection" ballot of the Australian Labor Party, in which candidates

in each locality have been selected by party members in that locality from those offering themselves for the preselection vote.

PRIMARY EDUCATION: see ELEMENTARY EDUCATION.

PRIMATE (from *prima sedes*, "first see"), an ecclesiastical title used of a bishop who has precedence over a number of other bishops. The term was applied in the 4th and 5th centuries to both secular officials and ecclesiastics; thus the Theodosian code (438) mentions primates of towns, districts, and fortified places (*primates urbium, vicorum, castellorum*), and a pragmatic sanction of Justinian I mentions primates governing a district, *primates regionis*. During the Middle Ages *primas* also seems to have been used loosely for "head" or "chief," since the word itself means only the one who holds first place.

In the Christian Church primate was one of several titles, others being metropolitan, exarch, and patriarch (*qq.v.*), employed to designate a chief bishop who had certain rights of superintendence over an entire district or area. At the Council of Nicaea (325) the title was assumed to embrace metropolitans, with authority over the bishops of an eparchy or province, and also bishops of high position—especially those later to be called patriarchs (the bishops of Rome, Alexandria, Antioch, and Jerusalem), but also those of "other eparchies" as well (perhaps the bishops of Heraclea, Ephesus, and Caesarea). After the Council of Nicaea the ecclesiastical title of primate came into use, more generally in Africa than in other areas. Then it came to be a formal title conceded by the pope to certain metropolitan bishops who possessed authority over several other metropolitans and were appointed, at the same time, vicars or legates of the Holy See. The False Decretals attempted to strengthen and perpetuate the authority of primates, but the office gradually became more or less honorary.

In the Roman Catholic Church primates are those metropolitan archbishops whose sees, by reason of antiquity or prominence, are the primary sees of a region or nation. Apart from the special case of the pope, who has among his titles that of primate of Italy, primates do not possess any jurisdiction outside their own dioceses but only a limited and honorary right to precedence. An exception to this is the bishop of Esztergom (Gran) who, with rank as primate of Hungary dating back at least to the 14th century, enjoys a measure of true primatial authority.

In the Church of England, the overlapping of the title is illustrated: the archbishop of York still bears the title of primate of England and the archbishop of Canterbury is primate of all England. (F. R. McM.)

PRIMATES, the order of mammals that includes tree shrews, lemurs, tarsiers, monkeys, apes, and men. Linnaeus distinguished the Primates as the highest ranking and most completely developed of all animals. Now, as in Linnaeus' time, this order is regarded with particular interest, for in the study of primate evolution man traces, however haltingly, his own family tree.

Other articles deal with the body systems and natural history of the Primates: APE; LEMUR; MAMMAL; MAN, EVOLUTION OF; MONKEY; TARSIER. This article, concerned mainly with the relationships, evolution, and behaviour of the Primates, is arranged as follows:

I. General

1. Evolutionary Trends
2. Characteristic Features

II. Classification and Survey

A. Primitive Primates (Prosimii)

3. Chimpanzees
4. Gorilla
5. Man

III. Origin and Relationships

IV. Behaviour of the Primates

1. Intelligence
2. Temperaments
3. Socialization

I. GENERAL

1. Evolutionary Trends.—The early Primates lived in an environment in which quick reaction to the constantly changing surroundings in treetops was essential for survival. When some of the higher Primates were compelled by changing environmental conditions to adapt to life on the ground, the special talents gained during the arboreal phase of their evolution were put to good use. The combination of brain expansion, neuromuscular coordination, and upright posture in the immediate forerunners of man permitted the development of more precise manipulative skills. At the same time, communication by facial expression and vocalization provided the opportunity for a greater degree of social cooperation, and led ultimately to the development of symbolic language. Finally, there appeared the higher faculties of insight, foresight, and reasoning, characteristic of man.

Most orders of mammals can be distinguished by outstanding specialized features. The order of Primates, by contrast, is relatively poor in such specializations: it comprises an evolutionary sequence that was isolated very early from the rest of the mammalian lines by an adaptation to life in the trees. Thus, one of the distinctive characters of the Primates is that they have tended to preserve a rather more generalized anatomy; they are to a large extent distinguished from other mammalian orders by a lack of extreme specialization. The arboreal existence effectively removed Primates from the competition of specialization required for survival among the terrestrial animals and provided a wide spectrum of other possible directions of evolution.

One of the notable evolutionary routes explored by Primates has led to an increased perfection of the controlling mechanisms of the brain, which in turn have been conditioned by an increased efficiency of the mechanisms of sight and touch, thus permitting a heightened responsiveness to a great number and variety of environmental situations. It may be said that primate evolution is characterized not so much by a progressive adaptiveness to a restricted type of environment as by a progressive adaptability to wider ranges of environment.

Broadly, the Primates may be defined as a natural group of mammals distinguished by the following evolutionary trends: preservation of a generalized structure of the limbs, with a primitive five-digit condition of the extremities; retention of certain basic skeletal elements (e.g., the clavicle); enhancement of the primitive free mobility of all the digits of the hand and foot for grasping purposes—especially that of the thumb and big toe; replacement of sharp claws by flattened nails; abbreviation of the snout or muzzle, leading to a "flattening" of the face; elabora-

tion of the visual apparatus; reduction of the organs of smell (which is of less importance for life in the trees than for ground-living mammals); preservation of a simple cusp pattern of the teeth; and progressive elaboration of the brain, mainly of the cerebral cortex and associated structures.

2. Characteristic Features.

—One of the striking features of the primate order, wherein it differs from other mammalian orders, is that its existing members fall into a graded series, or scale of organization, which (quite apart from the evidence of the fossil record) suggests an actual evolutionary trend leading from the most primitive (tree shrews) to the most advanced (man) within the order. As T. H. Huxley noted in one of his essays ("On the Relation of Man to the Lower Animals" in *Man's Place in Nature*; 1863): "Perhaps no order of mammals presents us with so extraordinary a series of gradations as this—leading us insensibly from the crown and summit of the animal creation down to creatures from which there is but a step, as it seems, to the lowest, smallest and least intelligent of the placental mammals."

In addition to the principal features of primate anatomy already enumerated, the following are important in identification and classification of the order. Proceeding up the graded series of modern Primates from tree shrew to man the skull changes considerably. The orbital cavities become relatively large and

face forward to varying degrees as well as laterally; the *foramen magnum* (through which the brain connects with the spinal cord) tends to be displaced from the posterior to the basal aspect of the skull; the braincase becomes relatively capacious and globular in form; the cavity of the middle ear becomes enclosed within the petrous bone or in a rounded expansion of this element, the *tymppanic bulla*; the external ear becomes connected with the middle ear by a bony tube called the auditory meatus; the labyrinthine turbinate complex within the nasal cavity undergoes simplification and the premaxillary element of the upper jaw becomes more or less reduced in proportionate size. In Primates of the Recent Epoch the occipital lobes of the brain, which accommodate the visual cortex, are conspicuously developed, the temporal lobes are relatively large, and the cerebral cortex is often richly convoluted.

In the dentition of Primates, the incisor teeth are in almost all cases reduced to two on each side of the upper and lower jaws; the premolar teeth, while preserving a simple structure, are also reduced from the primitive mammalian number of four to three or two; and the crowns of the molar teeth commonly have a tricuspid or quadricuspid pattern. The terminal phalanges are richly innervated, with highly sensitive tactile pads underlying the flattened nails. In the higher Primates the retina of the eye is characterized by the differentiation of a very sensitive central spot, the *macula lutea*, which provides a high degree of visual acuity. The alimentary system in most cases preserves a very simple pattern. The reproductive organs are likewise relatively

generalized in their structure: the testes commonly descend permanently into a pendulous scrotal sac; in the higher forms the uterus becomes simplified by the fusion of the uterine horns to form an undivided *corpus uteri*, and there is typically a rhythmic sexual cycle that, in most cases, is not restricted to a limited seasonal period; in passing from the lower to the higher Primates, there is a progressive elaboration of placental structure, which provides ever-improving conditions for the developing embryo. Not all these diagnostic characters of the Primates are developed to the same degree in the different existing members of the order; furthermore, in early fossil primate precursors some of the characters were only incipiently formed. The failure to recognize these temporal and gradual factors in the characters of various groups has led to contradictory views regarding the classification and evolutionary affinities of the Primates.

II. CLASSIFICATION AND SURVEY

The existing Primates may be divided into two suborders: the Prosimii, including the tree shrews, lemurs, and tarsiers; and the Anthropoidea, including the monkeys, apes, and men. Although there is good evidence for including tree shrews in the order Primates (see below), some authorities still regard this as problematical, for many features link them with the Insectivora (see INSECTIVORE for this viewpoint). That Primates stem from the Insectivora is certain; but at what stage in geologic time this offshoot occurred is unknown.

The first definite primate types are known to have existed in the Paleocene (58,000,000 to 70,000,000 years ago). These and later prosimians were primitive in the sense that they retained many of the characters of insectivores; e.g., long face, laterally placed eyes, and relatively small brain. The precise time of origin of the manlike forms, the Anthropoidea, is doubtful, but fossils of these Primates are first definitely known from the Oligocene (beginning about 12,000,000 years later).

The following taxonomic scheme for the Primates is one generally accepted:

- Suborder Prosimii, primitive Primates
 - Infraorder Lemuriformes
 - Superfamily Tupaiidae, tree shrews
 - " Lemuroidea } Madagascan lemurs
 - " Daubentonioidea }
 - Infraorder Lorisiformes, Asian and tropical African lemurs
 - " Tarsiiformes, tarsiers
 - Superfamily Tarsiidae
- Suborder Anthropoidea, manlike Primates
 - Superfamily Ceboidea, New World monkeys
 - " Cercopithecoidea, Old World monkeys
 - " Hominoidea, anthropoid apes and men

A. PRIMITIVE PRIMATES (PROSIMII)

1. Tree Shrews.—The tree shrews, which constitute the superfamily Tupaiidae, are exceedingly primitive small mammals of arboreal habitat widely distributed in southeast Asia. The living members of the group differ from other extant Primates in that

VEN HOUTRAND—PHOTO RESEARCHERS
TREE SHREW (TUPAIA). CLOSELY RESEMBLING A SQUIRREL, IS ACTUALLY THE MOST PRIMITIVE LIVING PRIMATE

all the digits of the hand and foot are furnished with sharp claws, and the brain is of relatively simpler construction. They are divided into two subfamilies, the Ptilocercinae and Tupaiinae. The former is represented by one genus only, *Ptilocercus*, the pen-tailed tree shrews, and the latter by a number of genera such as *Tupaia*, *Anathana*, and *Urogale*. The pen-tailed tree shrew is nocturnal, and in many features of its anatomy (particularly the brain) it is more primitive than the other tree shrews. The Tupaiinae are diurnal creatures and vary somewhat in their habits, the larger genera being more frequently found in forest undergrowth than in the higher branches of the trees. Like many tropical squirrels, some Tupaiinae are strikingly coloured, with vivid shoulder stripes and other markings.

The Tupaiidae resemble the other Lemuriformes in the detailed construction of the skull and in certain features of the dentition. In the lower jaw, however, they preserve three incisors, though the third is much reduced, and in the genus *Urogale* it has almost disappeared (as it has completely in all the higher Primates). The orbital opening is completely encircled by a bony ring; and the tympanic bone, which supports the eardrum, forms a simple ring lying free within a bubble-like bony structure, the bulla. The brain (except in *Ptilocercus*) shows a significant expansion of the

BORLANDELLI—PHOTO RESEARCHERS

RING-TAILED LEMURS (LEMUR CATT), ROCK-DWELLING SPECIES OF SOUTH-CENTRAL MADAGASCAR

cerebral hemispheres, the visual area of the cortex having a complexity of structure matched, among mammalian groups, only in the superfamily Lemuroidea. The placenta and fetal membranes are intermediate in their structure between generalized insectivores and the more generalized anthropoids. The limbs of the tree shrews have a wide range of movement, and the mobility of the thumb and big toe permits grasping by a converging flexion in association with the other digits. The bushy tail of the Tupaiinae gives them a squirrellike appearance. They, and most lemurs, comb the long hairs of the tail with their procumbent lower incisors.

2. Lemurs.—The term "lemur" is usually taken to include the Lemuriformes, exclusive of the tree shrews, and the Lorisiformes, including the lorises, pottos, and bush babies. In past ages the lemurs were widely distributed over the Northern Hemisphere; the group is now more restricted. The lemuriform lemurs are confined to Madagascar and adjacent islands, while the lorisiform lemurs are widely distributed over the tropical regions of Asia and continental Africa. In general structure the existing lemurs show an obvious approximation to the higher Primates in the degree of development of the brain, in the functional adaptation of the limbs for grasping purposes, in the presence of flattened nails on the digits, and in certain features of the skull and dentition. They also show conspicuous differences and specializations; so much so that some older authorities have even questioned their inclusion among the Primates. Such dissent, however, has

found no support among later students of the Primates.

The characteristic features of the modern lemurs include: (1) a curious modification of the lower incisors, which, combined with the procumbent and styliform canines, constitute a fine dental "comb" used to groom the fur; (2) the development of a serrated membrane (sublingua) on the undersurface of the tongue; (3) a pronounced loop in the large intestine; (4) the retention of a modified claw on the second digit of the foot; (5) the presence of a naked area, or rhinarium, around the nostrils, an area that extends down the midline of the upper lip and binds the latter down to the underlying gum; (6) a simple placenta quite unlike that of the higher Primates; and (7) in the lorisiform lemurs, a distinctive pattern of the blood vessels of the limbs in which the main arteries break up into fine vessels forming a complex network. The dental formula of most of the recent lemurs is $\frac{2.1.3.3}{2.1.3.3}$; that is, on each side of the upper and lower

jaws are two incisors, one canine, three premolars, and three molars. The molars are of simple construction and possess either three or four cusps. Most lemurs have rather large eyes, which serve them well for their nocturnal mode of life.

Lemuriformes.—The lemuriform, or Madagascan, lemurs comprise two superfamilies, Lemuroidea and Daubentonioidea, the former being subdivided into the families Lemuridae and Indridae. All lemuriforms are characterized by the possession of an intrabullar tympanic ring, and by the forward extension of the palatine bone to form part of the inner wall of the orbital cavity. The Lemuridae have an elongated snout, large and mobile ears, and long furry tails. The ring-tailed lemur (*Lemur catta*), commonly seen in zoological gardens, is conspicuous for its blackish tail ringed with white. The ruffed lemur (*L. variegatus*) is larger, sometimes as large as a mastiff terrier; it has a ruff of long hairs and a variegated coat ranging between dull white and black or sometimes reddish. Other species of the Lemuridae include the black lemur (*L. macaco*), brown lemur (*L. fulvus*), and the mongoose lemur (*L. mongoz*). Much smaller are the dwarf lemurs (*Cheirogaleus*) and mouse lemurs (*Microcebus*); these attractive little creatures are entirely nocturnal. They become inactive and estivate during the dry season, curling up in a nest of leaves and sustaining themselves on fat resources accumulated mainly in the base of the tail. They have large eyes and an abbreviated muzzle.

The Indridae include the largest of the living lemurs; they are distinguished from the Lemuridae by the loss of the lower canine and one of the upper and lower premolars, their dental formula thus being $\frac{2.1.2.3}{2.0.2.3}$. The hind limbs are long, permitting the

animals to leap easily from branch to branch. The tail is sometimes rather short, and the external ear tends to be concealed in the long silky hair on the side of the head. In general the Indridae are thoroughly arboreal. They are exclusively vegetarian, living on the leaves and buds of their native trees; for this reason they

are difficult to maintain in captivity and are infrequently seen in zoological gardens.

A remarkable exception to the usual morphology of the Madagascan lemurs is found in the aye-aye (*Daubentonia*), the sole surviving genus of the superfamily Daubentonioidea. This extraordinary creature possesses large rodentlike incisor teeth, while the canines are absent and the postcanine grinding teeth are grossly reduced. It has large ears, a long bushy tail, and well-developed claws on all the digits except the big toe (which is freely opposable and has a flattened nail, as in Primates generally). The third digit of the hand is curiously elongated and attenuated and is used to extract the animals' principal food, the larvae of wood-boring beetles, from crevices in the bark of trees. The brain of the aye-aye is also unusual, differing from all other modern lemurs in the convoluted pattern of the cerebral cortex and in the relatively large size of the olfactory bulbs. Indeed, in their general configuration, the cerebral hemispheres show a surprising resemblance to those of carnivores of the same body size. In one respect, however, the brain does conform with that of prosimians generally—in possessing a distinctive fissure known as the calcarine sulcus, which extends longitudinally through the medial aspect of the visual cortex. The alimentary tract shows the characteristic lemurine loop in the large intestine. Because of its unusual characters the aye-aye has been a subject of considerable discussion, some of the early 19th-century naturalists actually supposing it to be a rodent. It is now classified as a very aberrant lemur, but it is likely that it diverged from the other Lemuriformes at a very early time. For example, in its dentition it has followed a trend quite opposite to that of lemuriform evolution in general. In the Lemuroidea the upper incisors are reduced (together with a corresponding reduction in the premaxillary bone of the upper jaw) and the lower incisors and canines became procumbent and styliform to form a dental comb; in the aye-aye both the upper and lower incisors are much hypertrophied and there is no dental comb. Unfortunately the fossil evidence for the evolution of the aye-aye is practically unknown, the only available specimen being the Pleistocene form from Madagascar which was in all respects like the modern genus except for its larger size. Because of its aberrant dental morphology, it has been suggested that *Daubentonia* represents the terminal product of a divergent line of lemuroid evolution that possibly originated at the beginning of the Tertiary Period from a group of extinct Primates, the Apatemyidae. The Apatemyidae was also characterized by enlarged first incisor teeth together with a numerical reduction and retrograde changes affecting the rest of the dentition. This conjecture, however, receives no strong support from the fossil record, and there are reasonable arguments against it.

Lorisiformes.—The lorisiform lemurs constitute a single family Lorisidae, which is subdivided into two subfamilies, Lorisinae and Galaginae. Of the former, two genera, *Loris* and *Nycticebus* are found in southern Asia and two others, *Perodicticus* and *Arctocebus*, in tropical Africa. They are all arboreal creatures, moving with a slow, delicate crawl. The muzzle is short; the eyes are very large, in correlation with their strictly nocturnal habits; and the tail is either reduced in size or absent. *Nycticebus* is the slow loris, and *Loris*, because of its slender elongated limbs, is the slender loris. The various species of *Perodicticus* and *Arctocebus* are called pottos and angwantibos. The subfamily Galaginae comprises two genera, *Galago*, the bush babies, and *Eutloria*, which inhabit the equatorial forests of Africa. Both are active creatures with considerably elongated hind limbs used in leaping from branch to branch.

(Left) Slow loris (*Nycticebus coucang*), found in southeastern Asia and known for its deliberate and unhurried pace. (Right) Bush baby (*Galago*), a small arboreal lemur inhabiting the equatorial forests of Africa

KINNE—PHOTO RESEARCHERS

The Lorisiformes differ from the Lemuriformes in certain features of the skull, particularly in the auditory region, for the tympanic ring is not enclosed within a bony bulla but is applied to its outer surface, sometimes being extended into a short tubular channellike auditory meatus. It has commonly been assumed that the intrabullar tympanic ring of the Lemuriformes is a specialized and divergent feature, but it has recently been argued that it is really a primitive feature characteristic of the basal Primates. For one thing, the simple annular form of the tympanic bone is an embryonic character found in all the Primates in the early stages of fetal development. For another, its intrabullar position is characteristic of the most primitive extant Primates, the tree shrews (see above), and is also present in some of the Early Eocene Primates whose skulls have been preserved. Thus the Lorisiformes appear to represent a more advanced stage of development than the Lemuriformes. This conclusion is supported by the evidence of the brain, for in some lorisiform types the convolutional pattern of the cerebral cortex resembles closely that of the monkeys.

3. Tarsiiformes.—The infraorder Tarsiiformes is represented today by a single genus, *Tarsius*, which inhabits the tropical forests of Borneo, the Philippines, Celebes, and Sumatra, and also some of the lesser islands of the Malay Archipelago. It is a small nocturnal creature about the size of a marmoset, with a somewhat bizarre appearance because of its disproportionately large eyes; prominent, mobile ears; long tail (naked except for a terminal tuft of hair); expanded disc-shaped pads on the terminal digits of the hands and feet; and elongation of the hind limbs for saltatory, or leaping, functions.

Of the modern tarsiers, three different species, each comprising a number of subspecies, are usually recognized, though some authorities have doubted whether these distinctions are really valid. In its general anatomical character the modern tarsier occupies a position somewhat intermediate between the lorisiform lemurs and the New World monkeys. At the same time it presents a remarkable mixture of features: (1) primitive; (2) lemuroid; (3) specialized; and (4) advanced, or monkeylike.

1. Of the primitive characters, those of the dentition are perhaps the most obvious. The dental formula is $\frac{2.1.3.3}{1.1.3.3}$. The

incisor teeth are implanted vertically in the upper jaw, and are only slightly procumbent in the lower jaw. The premolars are very simply constructed, being predominantly unicuspid. The molars preserve a generalized pattern, the upper teeth being tributercular, and the lower having three main cusps in the anterior half and a hollowed-out basin (the talonid basin) in the posterior half. The digits of the hand and the carpal bones of the wrist also preserve a primitive arrangement. The cerebral hemispheres are practically smooth except for a deep calcarine sulcus on the medial aspect of the visual cortex, and the commissure linking the hemispheres across the midline (*corpus callosum*) is short and attenuated, as it is in some insectivores. The cerebellum is extremely simple in its convolutional pattern. The alimentary tract is remarkably generalized, lacking the elaborate colonic loop characteristic of the lemurs. The uterus is bicornuate.

2. The lemuroid features include a sublingua on the under surface of the tongue (but not serrated as it is in modern lemurs); an elongation of the fourth digit of the foot; an opposable big toe; an elongation of the navicular and calcaneal bones of the ankle similar to, but surpassing, that of the bush babies; claws on two of the pedal digits; an expansion of the orbital cavity of the skull; certain details in the pattern of cells of the lower visual centres of the brain; and the conformation of the ossicles of the middle ear.

3. The specialized features of *Tarsius* are the inordinate size of the eyes, which has led to a marked compression of the nasal cavities; the unusually mobile and rather batlike ears; the discoid pads on all the digits, which enhance their grasping power; the excessively elongated calcaneal and navicular bones, which provide power for leaping considerable distances; the partial fusion of the tibia and fibula; the mobility of the joints between the skull and the neck vertebrae, which allows the head to be turned

through 180°, so that it can face directly backward; and the curious naked tail, sometimes with papillary ridges on its ventral surface, which can be pressed firmly against a vertical branch as a sort of strut to help support the animal when clinging.

4. The advanced, or monkeylike, characters of *Tarsius* include a restriction and simplification of the nasal cavity associated with retrogressive changes in the olfactory parts of the brain; the formation of a well-developed *macula lutea* in the retina, very similar in structure to that of the marmosets; the rounded braincase; the basal position of the *foramen magnum*; the separation of the orbital cavity from the temporal fossa of the skull by a bony partition (which, however, is incomplete); the formation of a tubular auditory meatus; the extensive area and intrinsic elaboration of the visual cortex; the absence of a naked rhinarium; the mobility of the lips, which permits changes in facial expression; the advanced development of the placenta; and some features of the external genitalia.

Considering this mixed assemblage of anatomical characters, it is not surprising that in the past authorities have expressed contradictory views on the taxonomic position of *Tarsius* among the Primates. Those zoologists who have been most impressed with its monkeylike characters have separated the tarsoids from the lemurs and included them with the higher Primates in a common group, the Haplorhini. Those who have taken fuller account of the lemuroid features of the early fossil tarsiers believe that the line of distinction is not sufficiently abrupt to justify such a taxonomic separation from the lemurs. In the now widely accepted scheme of classification the Tarsiiformes are included with the lemurs and tree shrews in a common suborder, Prosimii, while their distinctive features are recognized by granting them a separate infraordinal status. This classification reverts to the opinion expressed many years ago (1846) by H. Burmeister in his classic monograph on *Tarsius*, in which he postulated that the modern tarsier is probably more closely related to the lemurs than to the higher Primates. In fact, in respect of their dental characters, it is by no means easy to distinguish some of the Eocene tarsoids from the Eocene lemurs (e.g., the genus *Caenopithecus*). It seems probable, therefore, that they originated from a common group of Paleocene prosimians and then became rather rapidly diversified.

The paleontological evidence also demonstrates that some of the extreme tarsoid specializations evolved very early in Tertiary times, and hence it has been surmised that at least some of the simian characters of the modern tarsier may be the result of evolutionary parallelism.

B. MANLIKE PRIMATES (ANTHROPOIDEA): MONKEYS

The monkeys comprise two main taxonomic groups, the New World or platyrrhine monkeys (superfamily Ceboidea) and the Old World or catarrhine monkeys (superfamily Cercopithecoidea). The terms "platyrrhine" and "catarrhine" refer to the disposition

HERMES FROM NATIONAL AUDUBON SOCIETY

LION MARMOSET (*LEONTOCEBUS ROSALIA*)

of the nostrils, which in the former case are placed rather wide apart and in the latter close together; this distinction, however, is not always very clear. In spite of their general resemblances, the two groups exhibit certain contrasting features that suggest an early divergence in their evolution. For example, the auditory region of the skull is differently constructed: in the platyrrhines there is a conspicuous swollen auditory bulla with the tympanic bone forming a simple ring applied to its outer surface; in the catarrhines the inflated bulla has disappeared and the tympanic element is produced into an elongated auditory meatus. The pattern of the union of skull bones is also different. The more apparent features that distinguish the New World monkeys from the Old World monkeys are: their tendency to develop specialized prehensile tails; their lack of ischial callosities; and their possessing three, instead of two, premolar teeth.

1. New World Monkeys (Platyrrhines).—The ceboid monkeys are confined to South and Central America, reaching as far north as southern Mexico. The group includes two families: Callithricidae (or Hapalidae), the marmosets generally, including the tamarins; and Cebidae, the larger platyrrhines, comprising the subfamilies Cebinae (capuchins and squirrel monkeys), Alouattinae (howlers), Callicebinae (titis), Aotinae (douroucoulis), Pitheciinae (sakis and uakaris), Atelinae (spider monkeys and woolly monkeys).

The Callithricidae contain the smallest and in some respects the most primitive of the extant monkeys, the marmosets; the closely related tamarins include monkeys with long canine teeth. Some authorities have recognized as many as nine different genera of the family.

The Cebidae are all thoroughly arboreal, and many of them have prehensile tails, which they use in hanging or swinging from the branches of trees or even for grasping objects such as food. The thumb is commonly reduced in size and only slightly opposable. Like all monkeys, they are distinguished from the lower Primates by certain features of the skull, in particular the complete separation of the orbital cavity from the temporal fossa by a bony wall. In some genera they have been observed to have a sexual cycle accompanied by a slight menstrual flow.

Marmosets and Tamarins.—

All retain sharp, curved claws on all the digits except the big toe, which bears a flattened nail; the thumb is not opposable; and the brain, though relatively large, is covered by a cerebral cortex almost devoid of convolutions. Except for one genus, *Callimico*, marmosets show a specialized loss of the last molar teeth, their dental formula thus being $\frac{2.1.3.2}{2.1.3.2}$, but even in *Callimico*, and indeed in the Cebidae (see below), the last molar tooth is much reduced in size and may be absent altogether as an individual variation. The molar teeth preserve a primitive tritubercular pattern.

Marmosets normally give birth to twins, or sometimes triplets; in all other monkeys and higher Primates multiple births occur only occasionally. So far as is known, they have no restricted breeding season and no regular menstrual cycle. They are largely insectivorous but also feed on fruit, seeds, leaves, and shoots. One of the commonest genera, *Callithrix* (or *Hapale*), is characterized by large ears associated with conspicuous tufts of whitish hair and by a tail ringed with black and gray hair.

The tamarins (*Leontocebus*) are distinguished by the length of their canine teeth and by the absence of ear tufts. One of them, the lion marmoset, is particularly attractive because of the mane

(*CEBUS CAPUCINUS*)

of long orange-coloured fur around the face. In captivity marmosets are delicate and nervous creatures, requiring for their well-being a constant temperature of about 75° F (about 24° C). The genus *Callimico*, a small and rather rare monkey, with a long tail, has been much discussed by taxonomists. Like other marmosets, its digits are furnished with claws, but the possession of a third molar tooth and certain resemblances of the skull to that of the squirrel monkey led to the view that it should be placed with the Cebidae. However, primatologists today regard it as more closely allied to the tamarins, though its unusual features have persuaded some to assign it to a distinct subfamily of the Callithricidae, the Callimiconinae.

Capuchins and Squirrel Monkeys.—

The subfamily Cebinae comprises the capuchins (*Cebus*) and the squirrel monkeys (*Saimiri*). The small capuchin monkeys, so named because the peak of hair on the top of the head recalls the peaked hood of Capuchin monks, make attractive and lively pets, and are said to display considerable intelligence. The squirrel monkeys (*Saimiri*) are small creatures characterized by an exceptional elongation of the occipital region of the skull and by a brain which, relatively speaking, appears unusually large. Their long tail is not prehensile.

Howlers and Titis.—The Alouattinae comprises the howler monkeys (*Alouatta*), which have an exaggerated hyoid bone distended in the form of a hollow shell, a condition that greatly amplifies the sound emitted. The vertical ramus of the lower jaw is expanded to cover the enlarged hyoid. The howlers are large animals that range through the forest in bands of a dozen or more; their roaring can be heard for several miles. The males have a conspicuous beard. The long tail is exceptionally prehensile, its tip being provided with a naked surface of skin covered with papillary ridges to give a firm grip.

The Callicebinae comprises one genus, *Callicebus*, the titi (tee-tee) monkeys, small slender creatures with a long bushy tail only moderately prehensile. Titis, mainly found in the forests of Brazil, have been regarded by some as even more primitive than the marmosets. Their dentition certainly presents very generalized characters, the canines being but slightly projecting and the premolar teeth preserving a very simple unicuspid form.

Durukulis and Sakis. The night monkeys of Central and South America, from Nicaragua to Paraguay, are colloquially known as durukulis. They constitute the subfamily Aotinae. Because of their exclusively nocturnal habits, unique among monkeys, and because they are not easily kept in captivity, little is known of their behaviour. They possess large eyes with a retina of a nocturnal type, which in its sensory receptors lacks cones and is entirely constructed of rods. The ears are diminutive and partly hidden beneath the thick fur. Because of the superficially apparent absence of external ears these monkeys have been given the generic name of *Aotes*. A white patch of fur above the eyes, together with the rounded face, gives them a somewhat owl-like appearance so that they are also referred to as owl monkeys. The tail is long but not prehensile, and the thumb is quite well developed. They are less vegetarian in their diet than many platyrrhine monkeys, feeding more on insects, eggs, and small birds. Although they possess a retina composed purely of rods, the retina shows a specialized central spot, the *macula lutea*, and in this respect they parallel the condition in *Tarsius* (see above). It is difficult to explain the presence of a macula in these two Primates, for it is assumed to be a device in the higher Primates for accentuating the visual discriminatory functions served by cones. In both cases the macula may perhaps be a vestigial structure that has persisted from evolutionary predecessors of diurnal habits who had a cone retina and the normal type of macula. Certainly this seems the most probable explanation of the macula in *Aotes*, whose cone-free retina is unique among the Anthropoidea and is undoubtedly to be regarded as a secondary adaptation. It now seems clear that the macular formation in the retina first appeared at the tarsoid level of primate evolution, and is thus phylogenetically much more ancient than has been commonly supposed.

The sakis (Pitheciinae) have markedly procumbent lower incisors, widely placed nostrils, a bushy but nonprehensile tail, and a comparatively well-developed thumb. The different genera of this subfamily show considerable variation in coat colour, and in most of them the long hair on the side of the head forms rather conspicuous whiskers.

Spider Monkeys and Woolly Monkeys.—The subfamily Atelinae includes the spider monkeys

(*Ateles*), which are the arboreal acrobats par excellence of the New World monkeys. Their long forelimbs are used for swinging from bough to bough—a method of locomotion termed brachiation. While the fingers are long and serve as powerful hooks for suspension from branches, the thumb is small and vestigial. The long tail is marvelously prehensile, and the naked skin on the ventral surface of its tip is employed as a highly sensitive tactile organ. Furthermore, the motor region of the cerebral cortex has been shown by experimental studies to include an unusually large area for controlling the complex prehensile functions of the tail. The spider monkeys are of particular interest to comparative anatomists because in many details of their limb structure and body proportions they parallel to some degree the gibbons of the Old World (see below) which have developed arboreal activities of a similar kind. The resemblance is particularly noticeable in the case of some of the Miocene gibbons, which had not fully achieved the more extreme specializations of the modern gibbons. Closely allied to *Ateles*, and included in the same subfamily, are the genera *Lagothrix* and *Brachyteles*. *Lagothrix* includes the woolly monkeys, which have a closely set pelage of soft fur and a moderately well-developed thumb. *Brachyteles*, in its general appearance and anatomical structure, represents an intermediate type that links *Ateles* with *Lagothrix*.

2. Old World Monkeys (Catarrhines).—The catarrhine or Old World monkeys constitute the superfamily Cercopithecoidea, which consists of only one family, the Cercopithecidae. The family is further subdivided into two subfamilies, the Cercopithecinae and the Colobinae.

The cercopithecoid monkeys are superficially similar to some of the larger ceboid monkeys, but they are more specialized in certain respects and more advanced in others. The specialized features are exemplified by the development of ischial callosities; by the presence either of cheek pouches or an elaborately constructed stomach; and by the bilophodont character of the dentition (the anterior and posterior paired cusps of bilophodont molars are united by strong transverse crests). The first and second lower molars commonly lack the fifth cusp, called the hypoconulid, while the last molar is usually extended back to form a conspicuous heel, called the talonid. The advanced features are the expansion of the cerebral cortex; the greater opposability of the thumb (in many genera); the more flattened nails on the digits; the more efficient type of placentation; and the regular menstrual rhythm. None of the catarrhines has a prehensile tail and many are not predominantly arboreal in their habits. The similarities between these progressive characters and certain features of the anthropoid apes led some past authorities to place

the catarrhines and apes in a common group, a classification that seemed further justified by the fact that certain precipitin reactions of the blood suggest fairly close affinities. On the other hand, as will be seen, there are marked structural contrasts that most primatologists now consider sufficiently significant to require a taxonomic separation of the catarrhines and the apes. The Old World monkeys have a wide geographical and climatic distribution, for while most genera inhabit the tropical regions of Africa and Asia, some reach as far north as Tibet, China, Japan, and the Himalayan Mountains, and (in the case of the baboons) as far south as South Africa. In Pliocene and Pleistocene times some also spread into central and southern Europe.

The subfamily Cercopithecinae are characterized by the consistent presence of cheek pouches for temporary food storage and by well-developed thumbs. They are less arboreal than the Colobinae. The tail varies considerably in its length and may be absent altogether. The stomach is of simple construction.

Macaques.—The various species of the genus *Macaca* (macaque monkeys) are perhaps the most adaptable of the cercopithecines and, although very able climbers, some have become almost entirely terrestrial. They range over southeast Asia from China and Japan to India, also extending into North Africa, where they are found in Algeria and Morocco. A small colony of the North African species, which is sometimes known as the Barbary ape, is still maintained on the Rock of Gibraltar, being fed and cared for by the local populace. Macaques are hardy animals and flourish in captivity. They are mostly omnivorous; one species (*M. irus*), common in Malaya, is colloquially termed the "crab-eating macaque" because it frequents coasts and estuaries, feeding on crustaceans and mollusks that it gathers at low tide. The most well-known macaques are the rhesus monkeys (*M. mulatta*), invaluable subjects in biological and medical research; these monkeys were used in solving the puzzle of blood groups in man and are now being used, among other purposes, in solving some of the problems attendant to manned space flights.

Baboons and Mandrills.—The true baboons (*Papio* species) are terrestrial creatures inhabiting open rocky country. They reach a formidable size and have a large projecting muzzle with terminally placed nostrils and (in the males) long ferocious-looking canine teeth. Baboons live in well-established communities

and, while predominantly vegetarian, they occasionally attack and eat small mammals. The sacred baboon (*P. hamadryus*) is the species represented in ancient Egyptian sculptures; today it is found in the Sudan, Somaliland, and southwestern Arabia. The males are distinguished by their long mane of hair. Some taxonomists assign the sacred baboon to a separate genus, *Comipithecus*. The gelada baboon (*Theropithecus*), which inhabits the mountains of Ethiopia, is very baboonlike in general appearance yet differs from the true baboons in that the nostrils are set back from the end of the muzzle and the latter is not so elongated and pointed. In certain features they show affinities with the macaques. The mandrills of west Africa resemble the baboons in their body proportions except that they possess only a short and almost rudimentary tail. They are distinguished by their large head and swollen muzzle, the latter marked by conspicuous blue ridges that contrast with the vivid scarlet skin of the nostrils. This remarkable coloration, combined with a white pointed "beard" and long and powerful canines, gives to the animal a particularly striking appearance. The genus *Cynopithecus* inhabits the Celebes. Although somewhat similar in general structure to the baboons, it is even more macaque-like than *Theropithecus*; its taxonomic affinities still remain rather obscure.

Mangabeys and Guenons.—The mangabey monkeys (*Cercopithecus*) are restricted to the tropical forests of Africa. They are more arboreal than the macaques, and, among other features, have long tails and conspicuous white upper eyelids. The cercopithecine monkeys (*Cercopithecus*), also called guenons, are the most abundant African types; more than 100 different species have been described. Their distribution covers most of the tropical areas of the continent south of the Sahara. They are usually rather small and lightly built animals of arboreal habitat, living mainly on fruit, leaves, and insects. The thumb is somewhat abbreviated, and the tail is always very long. The last molar teeth show some evidence of degenerative changes, and in the lower teeth the cusps are reduced to four, or sometimes three. Many of the cercopithecines are conspicuous for their attractive coloring, the coats varying in different species from a gray-black to a sombre green or a ruddy colour, and often contrasted with a white band on the forehead, a white patch on the nose, or ruffs of a white or yellowish colour. Closely related to the genus *Cercopithecus* is *Erythrocebus*, popularly referred to as the red guenon because

GIBBON (*HYLOBATES MOLUCH*), ONE OF THE MORE AGILE OF ANTHROPOID APES, OF THE MALAY REGION

of its brick-red coloration. It comprises about a dozen species and is widely distributed over the central region of Africa, extending as far north as the Sudan. The main interest of these guenons lies in the fact that they are only slightly arboreal in their habits, and are quite commonly found in open or sparsely wooded country of the savannah type. They move very rapidly on the ground. The thumb and big toe are less opposable than in the more arboreal cercopitheques.

Langurs and Allies.—The subfamily Colobinae is composed of the langurs, the proboscis monkey, and the guerezas. They are distinguished by the absence of cheek pouches and the development of a large and elaborately sacculated stomach in association with a strictly vegetarian diet. They are chiefly arboreal, feed largely on leaves and the young shoots of certain plants, and in captivity are much more delicate animals than the Cercopithecae. The langurs (*Presbytis* and *Rhinopithecus*) range over Malaya, India, and Ceylon, extending up to China, and into Kashmir and the southern slopes of the Himalayas. They are lightly built animals with abbreviated muzzles and long slender tails. One of the Himalayan langurs, from its footprints in the snow, may be responsible for the legend of the "Abominable Snowman." The genus *Rhinopithecus* (snub-nosed monkey), characterized by a short projecting nose, inhabits the high forests in the mountains of Tibet and northwest China. Closely related to the true langurs is *Nasalis*, the proboscis monkey, which is found only in Borneo. It is remarkable for its long, fleshy proboscis, which is much larger in the male and gives the animal a most grotesque appearance; in the female the shorter nose is turned up. The functional significance of the proboscis is unknown, but its marked development in the male indicates that it is primarily a sexual character.

The guereza monkeys (*Colobus*) are the only African representatives of the Colobinae; they comprise about 30 different species. Their arboreal specializations are accompanied by a shortness of the thumb, which may be little more than a rudimentary tubercle or even be absent altogether. Many of the guerezas have a mantle of long silky fur, parti-colored in black and white. The pelts are prized adornments among local populations, and at one time were exported in large numbers to Europe. (It has been estimated that, toward the end of the last century, as many as 200,000 of these beautiful creatures were being slaughtered annually for commercial purposes; fortunately, the demand for skins no longer exists to any significant degree.)

C. MANLIKE PRIMATES (ANTHOPOIDEA): APES AND MEN

Extant anthropoid apes approximate much more closely in their anatomical structure to the Hominidae than do the monkeys. They resemble man in the relative size and configuration of the

brain; in many details of the skull, dentition, and postcranial skeleton; in the tendency to adopt a semierect, or orthograde, posture (correlated with the shape of the thorax, the orientation of the shoulder girdle, the mode of attachment of the abdominal viscera, and other features); in the possession of a vermiform appendix; in the absence of a tail; and in the more efficient processes by which the embryo is nourished in the uterus. Of all these characters, the expansion of the brain is perhaps the most striking: for example, the brain of the large apes looks like a miniature human brain, and has the same basic pattern of convolutions and the same intrinsic structure of the cerebral cortex. Such differences as do exist are quantitative rather than qualitative, and even the quantitative ones dwindle when the endocranial cast of a gorilla is compared with that of extinct early hominids. These casts, which reproduce the cavity of the braincase, indicate the size and proportion of the brain itself because the latter fits the cranial cavity closely. In the Early Pleistocene hominid *Australopithecus*, the brain size approximated closely to that of a large gorilla, though it was probably larger in relation to body size. In certain minor characters of the skull and limb skeleton *Australopithecus* is closer to the apes than to modern man, so that the structural contrasts between man and apes become partly obscured when these fossil types are compared. On such evidence as this, taxonomists now generally agree that the Pongidae and Hominidae represent divergent branches of a common ancestral stock, a conclusion reflected in the classification, which includes the two families in a single superfamily, Hominoidea. The final justification for this scheme lies in the serological reactions of the blood, which clearly demonstrate that there is a closer affinity between these two groups than between either of them and the catarrhine monkeys.

The modern anthropoid apes constitute the family Pongidae. They are arboreal in varying degree and, in association with their habit of swinging arm over arm among the branches, have developed structural modifications such as the relative lengthening of the forelimb (with atrophy of the thumb) and a relative shortening of the hind limb. The orangutan and gibbon are the most exclusively arboreal and the most extreme brachiators, and in them, therefore, these specializations are most marked.

The subfamily Hylobatinae includes the gibbons; the Ponginae includes the orangutan, chimpanzees, and gorilla.

1. Gibbons.—The Hylobatinae comprises two genera, *Hylobates* and *Symphalangus*. Today gibbons inhabit southeastern Asia from Assam and Formosa to Java, Sumatra, and Borneo. These creatures of slender build and great agility move rapidly through the treetops, swinging along among the higher branches. But, in spite of their skill in

arboreal acrobatics, gibbons suffer severe injuries from falls, as is indicated by the frequency of healed fractures observed in gibbons found in the wild. They live in monogamous family groups of up to six individuals.

In some respects gibbons are more like the catarrhine monkeys than are the larger anthropoid apes; for example, they have well-developed ischial callosities and the convoluted pattern of the brain is relatively simple. But in all fundamental characters, such as the cusp pattern of the molar teeth, the proportions of the digits, the presence of a free vermiform appendix, the disposition of the thoracic and abdominal viscera, the absence of a tail, and the orthograde posture of the trunk, they are pongids. In their range of vocalization (they are the most vocal of the anthropoid apes) and in their aptitude for standing and walking on the ground on two feet, they offer points of particular interest in relation to the ultimate origin of the Hominidae.

2. Orangutan.—The orangutan (*Pongo pygmaeus*) is now confined to the forests of Borneo and Sumatra, but in Pleistocene times it extended its range as far north as China. As mentioned

above, it is highly specialized for arboreal life, and only rarely descends to the ground. It may reach a height of four to five feet or more and, unlike the active and agile gibbons, usually swings slowly and deliberately from branch to branch. Orangs are fruit eaters, being particularly fond of the durian. They construct sleeping platforms of twigs among the higher branches of the trees.

They have long reddish hair, and are characterized by the pronounced laryngeal sacs in the neck and (in large males) by flanges of dense connective tissue over the cheek region. Orangs contrast with the large African apes in the rounded contour of the cranium and in the absence of projecting brow ridges, but in adult males the cranium is frequently surmounted by a prominent sagittal crest to which are attached the large temporal muscles.

3. Chimpanzees.—Chimpanzees are about the same size as the orang, but they are less specialized. Active climbers, they spend their life in forests, but often come to the ground; they then usually proceed on all fours, taking their weight on the soles of the feet and the bent knuckles of the fingers. On occasion they stand upright but do not normally walk in this posture. The larger chimpanzees (*Pan satyrus*) inhabit the forests of equatorial Africa. Over a limited range south of the Congo River is an interesting pygmy chimpanzee (*P. paniscus*), recognized by some authorities as belonging to a distinct genus (*Bonobo*). Its teeth are small and delicately constructed, and the skull, preserving infantile proportions, more closely resembles that of hominids than do those of the larger chimpanzees. Chimpanzees move about in small troops made up of a single family, or a group of families, and like the orang they construct crude nests of branches, usually high up in the trees, where they rest during the night. They do well in captivity and can be trained to undertake many complicated tasks, an aptitude that indicates a considerable intelligence. Because of this responsiveness, chimpanzees have made excellent subjects for experimental studies by comparative psychologists.

4. Gorilla.—The gorilla is the largest of the anthropoid apes and shows a marked sexual dimorphism. In adult males the cranium is surmounted by a prominent sagittal crest, which, in the living animal, gives a false appearance of a high vaulted skull, while the brow ridges are strongly developed and the canine teeth long and powerful. Males may reach a height, in a vertical position, of over five feet and a weight of 450–600 lb. The females are smaller, with much less exaggerated canine teeth, and only rarely show a sagittal crest on the skull. Like the other apes gorillas are characterized by the proportionately great length of

(LEFT) ROOT-GRINDER, FRANKFURT (M)—PUBLIX, (RIGHT) VAN NOSTRAND FROM NATION AUDUBON SOCIETY

GORILLAS, THE LARGEST OF THE MANLIKE APES

(Left) Mountain gorilla from the mountainous eastern region of the Congo (Right) A group of immature lowland gorillas inhabiting the rain forests of western Africa

the arms and the relative shortness of the thumb. However, they are only slightly arboreal in their habits, for they spend much of their daily life wandering about in the undergrowth of the jungle. On the ground they normally adopt a quadrupedal gait, sometimes described as an "obliquely quadrupedal" gait, because of the inordinate length of their powerful arms. Only incidentally, particularly in attack or defense, do they momentarily rear themselves into an erect posture. The limb proportions indicate that gorillas were originally arboreal brachiating apes which, because of their increasing size, have taken secondarily to a terrestrial habitat, limiting their arboreal activities to the large lower branches of the trees.

Like chimpanzees, gorillas inhabit equatorial Africa but cover a more restricted area. They live in groups of 20 or more individuals made up of a few families and, contrary to travelers' stories which were at one time commonly accepted, they are not aggressive by nature. Indeed, in the wild they appear to be rather shy and docile creatures and are almost entirely vegetarian. The modern gorillas comprise a single species, *Gorilla gorilla*, with two subspecies, the forest (lowland) gorilla, which is commoner, and the mountain gorilla. Some authorities separate the two forms as distinct species, *G. beringei* being set aside for the mountain gorilla. The latter is found in the wooded mountainous country of the eastern Congo. It is said to be more completely adapted for terrestrial life than the forest gorilla, the forelimbs being less elongated. The feet more closely resemble those of man in that the great toe is not so strongly abducted and opposable and the other toes are relatively shorter.

5. Man.—The latest product of the primate evolutionary sequence is the family Hominidae, which includes modern man (*Homo sapiens*) and his extinct precursors. The origin and evolution of the Hominidae, and the physical anthropology of the modern races of mankind, are fully discussed in other articles. However, it is appropriate here to refer briefly to the earliest-known hominids. These form a subfamily called Australopithecinae, and their remains have been found in South Africa and east Africa. Their outstanding characters are a small cranial capacity, which is not much greater than that of a large male gorilla; massive jaws; a dentition that conforms in its morphological details to that of *Homo*; and bones of the pelvis and limbs constructed basically on the hominid plan. The lower limbs clearly demonstrate that the australopithecines were bipedal creatures whose erect posture had not reached the degree of perfection found in modern man. The occipital region and the base of the skull also display fundamental hominid characters. The final proof that the Australopithecinae come within the category of the Hominidae has been supplied by the strong circumstantial evidence that they were capable of fabricating crude stone implements. Such implements were first discovered in stalagmitic deposits in South Africa, which also contain australopithecine remains (but no remains of any more advanced type of hominid). Later, a remarkably complete australopithecine skull was found at Olduvai, in Tanganyika, embedded in a layer containing not only stone implements of the Oldowan culture but also fragments that had evidently been struck off in the course of the manufacture of those tools.

The australopithecines date from the Lower Pleistocene, and, since there is evidence that by that time they were already diversified into different varieties or species, it may be inferred that they existed as a group at a still earlier date, at least by the Upper Pliocene. However, there still remains a serious gap in the fossil record between the generalized Miocene and Pliocene apes on the one hand and the earliest hominids on the other. So far as the later history of hominid evolution is concerned, the fossil record is reasonably complete. There is now available an almost continuous graded sequence linking the Australopithecinae through *Pithecanthropus*, or *Homo erectus* (of Middle Pleistocene date), to the more generalized "Neanderthaloids," and finally to *Homo sapiens*.

See further AUSTRALOPITHECINE; NEANDERTHAL MAN; MAN, EVOLUTION OF; RACES OF MANKIND; ANTHROPOLOGY, especially the section Physical Anthropology.

III. ORIGIN AND RELATIONSHIPS

During the Paleocene and Eocene ages there existed an exceedingly primitive group of Primates, the Plesiadapidae, which, judging from their morphology, were related to the Eocene lemurs as well as to the tree shrews, thus serving in some measure to link the two groups; it may well be that they were closely related to the ancestors of the tree shrews. The structure of the skull and the postcranial skeleton was of a very generalized type.

In Eocene times an extinct family of Lemuriformes, the Adapidae, extended over Europe and North America. Those found in Europe constitute the subfamily Adapinae, and are mainly represented by the genera *Adapis* and *Pronycticebus*. The former is known from several skulls as well as some limb bones. Its relationship to the modern Lemuriformes is made clear by the construction of the auditory region of the skull, the orbits being encircled by a complete bony ring; also the premolars and molars conform to the lemuroid pattern. On the other hand (as might be expected of a lemuriform of some 50,000,000 years ago), *Adapis* shows many exceedingly primitive features. The dental formula is $\frac{2.1.4.3}{2.1.4.3}$, that is, all four premolars of the generalized mam-

malian dentition were still present. The incisor teeth were not procumbent, the upper and lower canines were stout conical teeth of generalized type, and the dental comb had not yet developed. The *foramen magnum*, instead of slanting downward as it does in modern lemurs, faced directly backward as in lower mammals generally. The brain, as judged from an endocranial cast of the skull, was far more primitive than that of modern lemurs, being relatively small in size and with large projecting olfactory bulbs. Yet the temporal lobes of the cerebral hemispheres were large and prominent, a characteristic feature of the primate brain that evidently evolved very early in the history of the order. The significance of the expansion of the temporal lobe is probably related to the inference (based on clinical and experimental studies) that this part of the brain constitutes a mechanism for the "storage" of visual memories. Thus, its progressive development in Primates presumably enhanced the ability to profit from experience on the basis of visual cues, an aptitude highly important to arboreal creatures, since they depend far more on their visual than on their olfactory sense for self-preservation. The small size of the brain in *Adapis* is reflected in the small size of the braincase, and this, again, is correlated with a conspicuous development of a sagittal crest, which provides attachment for the temporal muscles of the jaw. The Eocene Adapidae of the New World are grouped in a separate subfamily, the Notharctinae, and contain several known genera, including *Pelycodus*, *Smilodectes*, and *Notharctus*. *Notharctus* is particularly important in the evidence that it provides for numerous jaws and teeth and two almost complete skeletons are known. In its cranial characters *Notharctus* is very similar to *Adapis*; it also has the same dental formula, although there is a difference in the construction of the molar teeth. In both the Old World and New World genera, a fourth cusp, the hypocone, has been added to the primitive tritubercular pattern of the upper molars. In *Adapis* this cusp is formed in the more usual manner by an upgrowth from the cingulum encircling the base of the tooth, while in *Notharctus* it apparently arises by fission of one of the other cusps, the protocone. This difference has led to the conjecture that the two genera evolved independently from more primitive lemuroids, a theory that receives some support from various earlier species of *Pelycodus*, from Paleocene and Lower Eocene deposits, which demonstrate the transition from the tritubercular to the quadritubercular molar pattern. One of the interesting features of *Notharctus* is that while the skull, dentition, and cerebral dimensions preserved many primitive features, the limb skeleton approximated closely that of modern lemurs except that it was more robustly constructed. This is an example of "mosaic evolution"; i.e., different anatomical systems developing at different evolutionary rates. This phenomenon is also seen among other mammal groups where the limbs approached the culmination of their development quite early in evolution. It seems that in such cases the animals first became adapted by their limb structure to one particular

type of environment and subsequently perfected their adaptation by development of the skull, dentition, and brain.

In Pleistocene times (which began more than 1,000,000 years ago), a variety of unusual types of lemur inhabited Madagascar. One genus, *Megaladapis*, reached considerable size, and in body weight was probably the largest Primate known to have existed. Its skull reached a length of about one foot, the facial skeleton was much elongated, and the limb bones were of massive size. The brain was comparatively small, with poorly developed frontal and occipital lobes and with a projecting olfactory bulb. The molar teeth were large, though constructed on the lemuroid pattern, and the lower incisors and canines were strongly procumbent. So far as can be inferred from the limb bones, the creature may have been preponderantly terrestrial in its habits, but, like the modern gorilla, also capable of moving about among the larger branches of trees. *Megaladapis* may even have survived until comparatively recent times: a French explorer, De Flacourt, who visited Madagascar in 1648, recorded that among the animals peculiar to the island was a large creature the size of a two-year-old calf with a rounded head and humanlike face, both fore- and hind feet like those of a monkey, and ears like those of a man. Other Pleistocene lemurs of Madagascar were astonishingly monkeylike in the facial skeleton, and in the shape and convolutional pattern of the brain. Indeed, the superficially simianlike skull of one genus, *Archaeolemur*, at first led some zoologists to consider it a true monkey. But a detailed study of the skull and teeth revealed specializations peculiar to lemurs. Moreover, it is now known that monkeys came into existence elsewhere at a very much earlier geological date, at least by the Oligocene Period. Still, the development of monkeylike lemurs in Madagascar demonstrates the well-established evolutionary principle that related groups of animals tend to develop similar characters independently (parallel evolution).

There is a serious gap in the fossil record of the lemurs between the Eocene and Miocene periods, but it seems clear that their evolution must have proceeded very rapidly during that time. It is not known when the Lemniformes reached Madagascar, but the comparative paucity of other mammalian groups on the island no doubt stimulated the wide diversification of the unusual lemuroid types that had evolved there by the Pleistocene Period.

The earliest evidence of loriforms comes from Early Miocene deposits (up to about 25,000,000 years old) in east Africa, which have yielded fossilized remains of a genus called *Progalago*, probably a precursor of the modern *Galago*. In the characters of the skull and dentition *Progalago* shows an interesting combination of features, some of which correspond to those of the modern Asiatic loriforms. The only trace of a fossil loriform in Asia is a single molar tooth from Pliocene deposits (up to about 10,000,000 years old) in India; it was assigned to the genus *Indraloris*.

During the Paleocene and Eocene periods, tarsoids were widely distributed over the world, about 25 genera having been recorded from deposits in Europe, Asia, and North America. Of the European fossils of Eocene date, some quite closely resembled the modern tarsiers, in particular *Pseudoloris*, a genus whose orbital cavities were unusually large and the front part of whose skull is almost identical in its general proportions to modern forms. The dentition also is similar, except that the most anterior tooth of the lower jaw (probably a canine) is greatly enlarged and there is a persistent, but vestigial, first lower premolar. There is some evidence (not conclusive) that in two other genera, *Necrolemur* and *Nannopithecus*, the hind-limb skeleton was already specialized to the extent that the tibia and fibula were already fused together in the lower part. This particular character, it should be noted, distinguishes at least some of the tarsoids from all other known Primates, for it does not even occur in the galagos (see *Loriformes*, above), whose hind limbs are otherwise specialized in the same way for leaping. A comparison of the modern tarsier with these ancient tarsoids (which existed about 50,000,000 years ago) indicates that the modern tarsier is a "living fossil"—a surviving representative of a group that, in the seclusion of the tropical forests of the Far East, has persisted with little change up to the present day.

The genus *Necrolemur*, grouped together with certain other Eocene types in the subfamily Necrolemurinae, is, in certain features of the skull and dentition, somewhat more generalized than the modern tarsier. However, it displays advanced features that suggest an incipient trend allying it more closely to the higher Primates. For example, the detailed construction of the base of the skull shows certain simian features, as does the extended tubular auditory meatus (even though the tympanic plate is still partly enclosed within the tympanic bulla). Again, the molar teeth have a quadritubercular pattern, which is a conspicuous advance on the primitive tritubercular molars of the modern tarsier.

The fossil tarsoids of North America, so far as they are known, extend from the Paleocene to the early part of the Oligocene. In general they show more aberrant specializations than their Old World relatives, but exceptions are found in a few genera, such as *Omomyss* and *Hemiacodon*, in which the dentition remains rather generalized. These types are included in the subfamily Omomyinae, the only subfamily of fossil tarsoids known to have been common to both the Old and New Worlds. A somewhat aberrant genus, *Tetonius*, is known from a fairly complete skull found in Lower Eocene deposits in Wyoming. The base of the skull with its greatly expanded auditory bullae, the large orbital cavities, the globular shape of the braincase, and the much reduced olfactory bulbs are all indicative of tarsoid affinities. The post-canine teeth are also very similar to those of *Tarsius*, but anteriorly the dentition is highly specialized by the loss of at least some of the incisors and the gross hypertrophy (excessive growth) of the lower canine. The last lower premolar is also enlarged and is compressed from the sides. This feature is more exaggerated in another family of American tarsoids, the Carpolestidae, in which the crown of the last premolar forms a sharp, elongated crest with a serrated edge. This may have served to crush or slice into the tough rind of fruit or the hard cuticle of insects. Since the Carpolestidae are known only from fragments of the jaws and teeth, their precise affinities remain uncertain. (Some authorities would even exclude them from the tarsoids.)

Probably the latest known fossil tarsoid is *Macrotarsius*, one of the Omomyinae from the Lower Oligocene of North America. Thereafter the paleontological history of the Tarsiiformes is completely unknown. Evidently most of their early ramifications became extinct without phylogenetic descendants, leaving only the modern genus *Tarsius*. This genus may have migrated to its present habitat from Europe, where, in Eocene times, there existed fossil tarsoids such as *Pseudoloris*, which perhaps included its early ancestors.

The evolutionary origin of the New World monkeys is still obscure. As already noted, they and the Old World monkeys show a degree of structural contrast that suggests the two groups must have diverged quite early in their phylogenetic history. The evidence of paleogeography supports this inference, for it seems that there have probably been no land routes between the Old and New Worlds available to tropical arboreal Primates after Eocene times. Unfortunately, the fossil record of the platyrrhine monkeys is very scanty indeed. Their earliest known representatives are two genera (*Cebupithecia* and *Neosaimiri*) found in Miocene deposits in Colombia, and one genus (*Homunculus*) from the Miocene of Colombia and Patagonia. All are quite similar to some of the modern ceboids. It has been suggested that the platyrrhines are descendants of the New World lemuriform genera *Notharctus*, but, on the basis of the comparative morphology of the different infraorders of the Prosimii, it is more reasonable to suppose that their ancestors were nearer to the Tarsiiformes and that the basal stock from which they have been derived may eventually be found among the diversified groups of extinct tarsoids that populated the American continent up to the early part of the Oligocene.

The origin of the Old World monkeys certainly dates back to the Lower Miocene, for jaws and teeth showing the typical bilophodonty of cercopithecoids have been found in east African deposits of this period. There is also evidence that their precursors were undergoing differentiation even earlier. Two small fragments of jaws from the Eocene of Burma have been regarded

by some authorities as the earliest representatives of the Old World monkeys. If this interpretation is correct, one fragment (assigned to the genus *Amphipithecus*) is of particular interest because it still retains a more primitive dental formula, which includes three premolars, though the most anterior of these is rudimentary and apparently in the process of disappearing. Apart from this somewhat equivocal evidence of Eocene monkeys, the earliest indubitable remains of the suborder Anthropoidea have been recovered from Oligocene deposits in Egypt. Of these the most important are a small lower jaw with the dentition well preserved, and the frontal part of a skull. The jaw has been given the generic name of *Parapithecus*. The structural details of individual teeth are remarkably primitive; indeed because of the generalized and undifferentiated form of the front teeth there has been some doubt whether the formula of the lower dentition should be 2.1.2.3, or 1.1.3.3; the latter is now generally accepted as correct. Since the molar teeth are not bilophodont, it has been suggested that *Parapithecus* is to be regarded as an early representative of the anthropoid ape sequence of evolution. But it is just as likely that this Oligocene genus belongs to the ancestral stock that gave rise to both anthropoid apes and catarrhine monkeys before the bilophodont specialization of the latter had become established. The skull fragment found in the same deposits in Egypt may well belong to *Parapithecus*—it comes from a small monkey of closely comparable size—but since it was not found in immediate association with the jaw, its generic identity is doubtful.

Two other genera from the Egyptian Oligocene, *Moeripithecus* and *Apidium*, have been interpreted, on the basis of portions of the mandible and a few teeth, as primitive catarrhine monkeys. However, this interpretation has not found general agreement, and the similarities in the structural details of the molar teeth between *Apidium* and *Oreopithecus* (see below) are very striking. A lower jaw found in Egyptian Oligocene deposits has been assigned to a new genus, *Oligopithecus*; it is perhaps to be regarded as a very primitive anthropoid ape. On the other hand, the very generalized character of the dentition has led some to believe that it represents an early stage in the differentiation of the Cercopithecoidea. A cercopithecooid genus of Pliocene date, *Mesopithecus*, is known from unusually well-preserved remains (including an almost complete skeleton) found in Greece, others also being known from Pliocene deposits in Czechoslovakia, southern U.S.S.R., and Iran. This fossil type, quite similar to the modern Colobinae, may have existed still earlier, for the few cercopithecooid jaws and teeth so far recorded from the Lower Miocene of east Africa have been tentatively assigned to the same genus.

The modern genus *Macaca* was well established and widespread by the Pliocene, and during the temperate interglacial phases of the Pleistocene it was a quite common inhabitant of central Europe. The modern colobine genus *Presbytis* has been reported from a Lower Pleistocene stratum in India. A baboonlike cercopithecooid, *Libypithecus*, is known from Pliocene deposits in Egypt, and *Simopithecus* (similar to the modern gelada baboon and in some species reaching a massive size) is found in the Pliocene and Pleistocene of east Africa. Extinct Pleistocene baboons, *Dinopithecus*, *Gorgopithecus*, and *Parapapio*, existed in south Africa, and remains of the modern genus *Papio* have also been found in Lower Pleistocene strata in northern India, Algeria, and Egypt.

Oreopithecus, of Lower Pliocene antiquity, which is known from fairly abundant remains discovered in lignite mines in Italy, has been the subject of considerable discussion because of its unexpected mixture of anatomical characters. It was usually grouped with the Cercopithecoidea, but the dental morphology has more recently led some authorities to identify it as a generalized type of anthropoid ape. The evidence based on portions of the limb skeleton (unfortunately not very well preserved) lends strong support to this interpretation, but its precise taxonomic position still remains doubtful. It has been assigned to a family of its own, *Oreopithecidae*, and it may represent a somewhat aberrant offshoot of the basal stock common to the cercopithecooid monkeys and anthropoid apes.

The geological record demonstrates that the anthropoid ape,

or pongid, sequence of evolution is of considerable antiquity. Mention has already been made of the little jaw of *Parapithecus* (see above), which some authorities regard as the earliest definite evidence of an anthropoid ape; this dates from the Oligocene Period. A mandible from the same Oligocene deposits is certainly that of a small anthropoid ape similar in its dentition to, but more primitive than, the modern gibbon; it has been given the generic name *Propliopithecus*. Later, in the early Miocene, a great many apes existed in east Africa, which are known not only from jaws and teeth but also from portions of the skull (one almost complete) and a number of limb bones. The smallest of these is a gibbonlike creature, *Limnopithecus*, whose dentition resembles quite closely that of *Hylobates*, while its limb skeleton is more primitive and displays a significant combination of cercopithecooid and pongid features, the latter in certain characters approaching those of the modern gibbons but by no means so specialized for brachiation. The limb bones are remarkably like those of the South American spider monkey in their proportions. Most of the larger apes from the east African Miocene are included in the genus *Proconsul*, which comprises more than one species ranging in size from that of a pygmy chimpanzee to a creature of gorilloid dimensions. Although the dentition is fundamentally pongid, the skull and limb skeleton of the smaller species show, like *Limnopithecus*, cercopithecooid features mingled with certain traits adumbrating the specialized features of the modern anthropoid apes. They were, it seems, anthropoid apes in the making and, while no doubt arboreal, were capable of running and leaping in the manner of the quadrupedal monkeys. The brain of *Proconsul* was relatively small and very cercopithecooid in its convolutional pattern. During the Miocene, there were also gibbonlike apes in Europe, represented by *Pliopithecus*. The greater part of the skull and much of the limb skeleton is known; like other Miocene apes, these types show cercopithecooid features that make it evident that *Pliopithecus* was not highly specialized for brachiation. During the Miocene and Pliocene periods, a genus of large apes, *Dryopithecus*, was fairly widespread in Europe and Asia, extending as far east as China, but apart from a single humerus and femur it is only known from jaws and teeth. The latter are mainly pongid with a few rather more primitive features. From the Siwalik Range of India, several other Pliocene types of ape have been recorded and assigned to distinct genera (e.g., *Sivapithecus*, *Pakiosimia*, *Bramapithecus*, *Sugrivapithecus*, and *Ramapithecus*), in some cases on rather fragmentary evidence. Of these the last is of particular interest, for the small size of the teeth (particularly the canines) and the relatively simple construction of the molars suggest that it was not far removed from the transitional phase in which, presumably, the hominid type of dentition derived from that characteristic of most Pliocene and Miocene apes. Indeed the view has been strongly advocated that *Ramapithecus* is to be regarded as an Early Pliocene hominid rather than as an anthropoid ape. The upper jaw of a Pliocene ape found in Kenya has been called *Kenyapithecus*, but its resemblance to *Ramapithecus* is so close that some authorities doubt that it can be distinguished from the latter genus.

The report in 1965 of two alleged new fossil primate species, uncovered in local Paleocene strata of eastern Montana, was met with mixed reactions. The species descriptions, based on several primitive primatolike teeth, were referred to a new subfamily created for them, the Purgatoriinae. Their status as a subfamily (and perhaps even as primates), however, awaited more positive evidence, studied opinion, and debate among paleontologists.

The descent of man and the fossil discoveries that illuminate his origins are treated in detail in the article MAN, EVOLUTION OF. (W. E. L. G. C.)

IV. BEHAVIOUR OF THE PRIMATES

The close similarity of Primates in their anatomy and physiology is, not surprisingly, paralleled by similarities in basic behaviour, or adaptive responses. Intellectually, man is far superior to apes and monkeys, but there is some overlap in ability between man and the subhuman primates. Primates as a group, excluding the lemurs, are generally superior to other mammals, with the possible

exception of the cetaceans (the porpoises and whales), whose intellectual capacities, apparently high, have not been fully investigated. The emotional and social differences that exist between man and the subhuman primates are in large part a consequence of their intellectual differences. It is primarily in the organization of his societies and the learned control of his emotions, and not in the primary physiological and motivational aspects of emotion, that man differs from the subhuman primates.

1. Intelligence.—Man is the only animal that has succeeded in controlling and modifying his environment to meet his own needs. Historical evidence suggests that only in the last several thousand years has man attained sufficient control over his physical and biological world to live more than a simple nomadic or agrarian existence. Subhuman primates remain at the nomadic level, as do some primitive human groups even today. It was only when man achieved social structure that he became free to explore the full intellectual capacities he possessed. His major achievements have been the products of the few among him—those rare individuals with the highest order of intelligence. The vast majority of men are incapable of intellectual creativity, and a not insignificant number are unable even to understand or to apply the accomplishments of the ablest. Thus, man, who as a species has had remarkable intellectual successes, probably has had little more than the minimal intellectual endowment to achieve the civilization that we know today.

There is no scientific evidence to prove that man is superior to other primates or even to other mammals in learning conditioned responses or in solving problems involving orientation in space. In memory tests in which language skills are not necessary (but could be helpful), chimpanzees perform as well as human children and almost as well as adults. But as intellectual tasks grow more complex, man's superiority rapidly becomes evident. Other mammals have at least the rudiments of all aspects of thinking that do not require verbalization. Man's ability to form concepts and to apply them in problem solution—his primary intellectual asset—is also present in apes and monkeys and even rodents, but to a far lesser degree. Rhesus monkeys have been trained, for example, to form concepts of redness and blueness and to apply these concepts. The acquisition of concepts is slow in subhuman animals; in a lifetime they can acquire relatively few. Man, on the other hand, forms thousands of concepts in a lifetime and can transfer them to his fellows who use them to form new and more abstruse concepts.

In laboratory experiments requiring the transfer of learning from problem to problem, chimpanzees and monkeys are the equal of normal young children and superior to severely retarded adolescents. In tasks requiring simple creativity, however, apes and monkeys lag behind normal human children. There are many successful performances of chimpanzees (and of orangutans, gorillas, and cebus monkeys to a lesser extent) in drawing, painting, and tool using, but the predominant behaviour trend is toward destructive rather than constructive use of materials.

The greatest gulf between man and subhuman primates is language. Subhuman primates use sounds and gestures to communicate; these mannerisms suffice for mutual protection and amicable group living. Since they also permit training and discipline of the young, they serve as a limited transfer of concrete culture from generation to generation. Man first verbalized his thoughts and transferred them from generation to generation, then much later he symbolized language, vastly increasing the transfer of knowledge in quantity, complexity, and accuracy through the written word. No ape or monkey shows aptitude for acquiring verbal language, although psychologists have devoted intensive efforts to teaching young apes to talk. Typically, the ape can acquire two or three words after many months of training, but the end results resemble the stage of language of 12–15-month-old human babies who may mime a few words but cannot put them together to express ideas. Moreover, each newly learned word tends to interfere with the words previously mastered.

The intellectual hierarchy within the primate order has not been fully established beyond placement of man at the top. The most inferior human representatives are inferior to normal apes and to

at least some monkeys. Chimpanzees appear to be superior to other apes, although the abilities of orangutans and gorillas have not been as thoroughly explored and may eventually place them on an intellectual level with the chimpanzees. Gibbons appear to be much inferior to other apes and to many monkeys as well. Macaques perform on most laboratory learning tests as well as chimpanzees, but they are inferior to them in the use of tools and in creativity. Spider monkeys appear to be almost as able as macaques on learning tests and to be superior to other South American monkeys. Cebus monkeys, on the other hand, approach chimpanzees in mastery of motor skills and tool using, but are inferior in most learning tests to chimpanzees, macaques, and spider monkeys. Primitive monkeys such as marmosets are clearly inferior to gibbons and to all other monkeys that have been tested. Lemurs appear to have less learning ability than any of the monkeys and apes; furthermore, on many standardized learning tests the lemurs are inferior to cats, dogs, and even pigeons.

2. Temperaments.—The basic temperaments of the primates present a paradox both intriguing and bewildering, for in all probability primates as a group are both the most affectionate and the most aggressive of all animals. Their fighting tendencies must have served them well in natural selection, and their strong affectional bonds for members of their species have made them the most effective social animals. Individually, primates are relatively weak and poorly armed, but the bonds that underlie the formation of relatively large, cohesive social groups also facilitate the use of their aggressiveness in cooperative group defense.

It would seem that an extremely aggressive animal is poorly devised to be a highly social animal. The resolution of this paradox, however, is found in the order of development or maturation of the affectional and the aggressive behaviours: habits of affection are firmly established before aggressive tendencies are allowed vigorous expression. Intimate affectional bonds are formed in all the major primate groups within the first weeks or, at most, first months of life, originating in the reciprocal affection of mother and infant.

Primates are relatively immature at birth and have a long infancy. Newborn human beings are almost completely helpless, being unable even to change position or to cling to the mother. Apes are also unable to move about at birth, but within a few days a chimpanzee can cling to its mother for support while she is moving. Gorilla babies either cling less tenaciously or have more cautious mothers, for the mothers move with one arm about the clinging baby during the first few months. Until four months of age chimpanzees and gorillas never leave their mothers, and then they begin to leave for only a few minutes at a time and for a distance of only several yards. Monkeys are much more mature at birth than human and ape newborn, and they can cling fairly well within only hours after birth. By the second day most monkey mothers need only occasionally to touch the clinging infant while they are moving. Except for langurs, which permit other females to hold their babies, monkey mothers seldom release their babies in the first weeks. Between two and four weeks, monkey babies play between their mother's legs but rarely leave her, and in the second month they may move several feet from her but never stay away for more than a few minutes at a time. Thus the mother-infant relationship in subhuman primates tends to be more intimate and more exclusive than that in human groups.

The mother is the infant's social center for the first one to three years of life, the duration being related to the rate of maturation, the social organization, and, usually, the spacing of births. Japanese and rhesus macaque mothers separate their infants at 10 to 12 months of age, when a new baby generally arrives. Baboons separate their infants at about 10 to 15 months but usually produce a new baby only every two years. Gorillas and chimpanzees separate their infants at three years, the usual period between births. In all these primates, however, the older offspring retain some physical proximity to their mothers for one to three years after separation, especially when sleeping and when seeking protection in times of danger. Gibbons are an exception in that they live in family groups with as many as four successive young ranging from newborn to young adult.

During the period of dependency, the mother-infant and infant-mother bonds are the closest of all primate affectional relationships, and the mother, not the infant, takes the initiative in weakening them, usually with great resistance from the infant. In the early months for the monkeys and somewhat longer for the apes, the mother nurses the infant, grooms it, cradles it, comforts it, protects it from threats, and provides its first social training. She sleeps with it in her arms or nestled against her body. She travels with it clinging to her ventral surface at first and on her back later. Her treatment is universally tender, tolerant, and solicitous. In laboratory studies of the rhesus, mothers rarely threatened or punished the infant until it was three months old, and even then the reprimands were mild. Gradually, negative treatment increased in frequency and severity, but even at a year the affectionate responses outweighed the rejecting ones. The primate infant in this same period stays close to the mother and clings to her or leans against her much of the time. It learns early to respond to her sounds and gestures and always returns to her when frightened or when the group is about to move off.

Affectional bonds impart to the infant, through the mother, basic confidence and security, which enable the infant gradually to go forth and explore its physical and social world. The first other living beings it encounters are the members of its own species, and because of the primary affectional bonds already established, it interacts with them in a friendly manner. In all large primate groups there is likely to be a clustering of births, and an exploring infant soon establishes primary contacts with age mates, or, lacking age mates, with young juveniles. Their interaction takes the form of increasingly complex patterns of play out of which develops the age-mate or peer affectional system. Laboratory data on the rhesus monkey indicate that the age-mate affectional system, which persists throughout the individual's life, is probably even more important than the maternal affectional system in converting the infant primate into a socially mature adolescent and adult. During the first year, monkey and ape babies spend increasing amounts of time with their peers while adults feed or rest. In the second year, monkeys spend most of the day with their peers; chimpanzees and gorillas reach this stage at about three years. As adolescents and young adults, monkeys associate almost exclusively with their age groups, more and more as sex-segregated groups with transient sexual pairing.

3. Socialization.—It is possible to reverse the normal developmental trends of affection and aggression by isolating monkeys in the experimental laboratory and thereby denying them any opportunity to form social bonds at the proper maturational stage. If affection is denied until aggression has matured, the normally social monkey, ape, or man becomes an asocial animal. Researches at the University of Wisconsin Primate Laboratory show that socially isolated male rhesus monkeys never adjust adequately to other rhesus monkeys, showing aggressiveness and failure to understand, utilize, or acquire the gestures and postures normally learned in infancy. The socially isolated female also has difficulty in adjusting. Rhesus females raised with little or no early social experience and impregnated by various techniques usually either ignored their first-born infants in spite of the infants' unending attempts to make maternal contact or treated them cruelly, sometimes to the point of maiming or killing them. Some of these indifferent or brutal mothers produced second babies, however, and all but one were either good or adequate mothers, indicating that they gained socialization experience from the association with their first babies. (Normally, female monkeys are good mothers to their first-born babies and tend to be more lenient with first offspring than with later offspring.)

If primates form affection for their fellows early in life and are not confined in cramped quarters, they adjust to each other with a minimum of quarreling and direct their later-maturing aggressions less to members of their own species and more to intruders from without. Laboratory observations on rhesus monkeys indicate that strong in-group affection is present among infants before the end of the first year, when true aggressive responses begin to appear. Dominance relationships then become more firmly established and, because each member learns its position with respect

to its fellows, social order is maintained with a minimum of fighting. Most field observations of monkeys and apes confirm the laboratory studies.

One aspect of the social paradox that has attracted attention is the role of dominant males within monkey or ape societies. Not only do these members defend their group from outsiders, but they accord special protection and special status to mothers with new babies and to all the young. Japanese macaques in some, but not all, troops display especially strong paternal behaviour. The most dominant males adopt infants of about 10 or 12 months of age when the females are delivering new babies, thus providing a transition for the infant between mothering and independent living. Dominant male baboons display very strong interest in new babies and tolerance of all infants up to about two years old, even adopting orphaned infants on occasion. Threat to an infant releases violent aggression in these males. Dominant male gorillas are reported to be especially tolerant and protective of infants. Adult male langurs show little or no interest in infants until they are close to one year of age, when young males establish contact with the dominant males; at that time the males tolerate the youngsters' advances and even embrace them. Male adult rhesus monkeys likewise are tolerant of the young and highly protective.

There is no report of any adult subhuman primate mistreating a youngster under natural circumstances, and there are numerous reports that adult males consistently break up any social situation where an older animal is abusing a younger one, whether it is a female threatening another female's infant or a juvenile or adolescent playing too roughly with smaller members of the group. Thus, the dominant males train younger and less dominant members to respect and protect the young. Among human beings the parental affectional system may break down, as a result of emotional and social disturbance, resulting in child beating or child abandonment; though society disapproves such abuses, privacy may mask them. Among monkeys and apes in the wild, the individual that fails to become socialized is driven from the group or killed before it reaches full maturity. In the laboratory, socially deprived male monkeys, like their female counterparts, show abnormal aggression in their relationships with infants as well as with their peers.

A striking finding in all subhuman primate groups thus far studied is the prevailing peacefulness of interactions within the groups. The emotional tone, however, varies among species, genera, and families. At one extreme among the apes are the mountain gorillas; calm and placid, they show minimal excitement and interaction and maximal group stability. They may be compared to the extreme introverts in human society. In contrast are the chimpanzees of Tanganyika, which show exuberance and joy in their interactions but very low group stability. Friends and acquaintances hoot and embrace warmly when they meet, interact pleasurably while they are together, then often separate to rejoin particular clusters or to join different groups. Their human counterparts are the extreme extroverts. Gibbons live in families with the male-female pair showing equality of dominance and a minimum of friction. The monkeys thus far studied tend toward stable groups dominated by one or more adult males, but the emotional tenor varies from the high excitability of the baboons and rhesus monkeys through the calmness of the Japanese macaques and langurs to the generally more quiescent behaviour of howling monkeys. In all groups, vocalizations and gestures appear to suffice for settling most disputes, and serious injury to other group members is infrequent.

Between groups of the same species, however, there may be a wide range of relations. There may be peaceful intermingling of two gorilla troops, for example, and yet each of these groups may display aggression or withdrawal when it meets still other specific groups. A rhesus troop may withdraw when it meets one troop but force withdrawal of a different group upon encounter. Leaders apparently learn their status among groups just as individuals learn their status within groups, thus minimizing actual destruction of the species. Moreover, ape groups may encounter monkey troops without evidence of aggression, or several species of monkeys may meet without incident and even sleep in the same tree.

There are close parallels between man and the various subhuman primate groups in the basic processes of group organization and interpersonal relationships. Different species vary in the nature of their social relations, suggesting underlying quantitative differences in physiology, which could well have resulted from gradual selection for the physical and biological environment to which the species had to adapt. In different isolated human societies one can approximate the range of group personalities that appear in the subhuman primates. There are some groups almost as placid and calm as the mountain gorilla, and other groups as excitable as baboons and chimpanzees.

Man started with the same basic drives and emotions as other primates and developed his culture to meet his special needs. His greater intelligence and more highly developed system of communication have enabled him to exert subtler controls over the members of his group and to channel responses through more intensive training of the young. Underlying these differences remain the deep-seated primate inclinations to form affectional ties that both satisfy the individual and hold the group together and impulses to aggress against personal interferences to protect the individual and, by extension, the group.

PRIME MINISTER, the name given to the head of the executive branch of government in countries with a parliamentary system. He serves under the chief of state, except in those rare cases in which the chief of state assumes the functions of prime minister himself. The origin of the title is to be sought in the period of absolute or nonparliamentary regimes when all ministers of government were simply servants of the sovereign and individually responsible to him for the management of their departments. One of them might exercise a predominant influence in fact, but not by any constitutional right. In France, however, with the advance of royal absolutism the cardinal duc de Richelieu was acknowledged in 1624 as *principal* or *premier ministre*; and Cardinal Mazarin succeeded him in this position in 1643. After Mazarin's death (1661), Louis XIV ruled without any chief minister; but the odium that ministerial absolutism had aroused in wide circles both in France and abroad remained long attached to the expression "prime minister," and it was only after an interval that its use in England in the sense with which we are here concerned was revived.

Great Britain.—The preponderance over other ministers of the crown that Cardinal Wolsey or Lord Burghley enjoyed in 16th-century England was short-lived; and in the 17th century, when Gilbert Burnet described the earl of Clarendon as "chief, or the only, minister," he was yet well aware that the style "first minister" was "a title so newly translated out of French into English that it was not enough understood to be liked, and every man would detest it for the burden it was attended with." Even in the 18th century it is more usual to find partnerships of two or three individuals, such as Marlborough and Godolphin, Harley and St. John, Stanhope and Sunderland, or Townshend and Walpole sharing the government. But the place vacated by George I when, from 1717, he ceased to attend Cabinet meetings, had to be filled by a single individual, and this presiding officer developed into a prime minister. Sir Robert Walpole, though he "unequivocally denied" the title, is usually regarded as the first prime minister, and during his long term of office (1721–42) he developed many of the attributes of premiership. He was master of his Cabinet; he insisted that his colleagues subscribe to the principles of his party; he dismissed his opponents; he dispensed the royal patronage; and, with reservations, he may be described as commanding a majority in the House of Commons. How novel, how unpopular, such a position still was may be gathered from the proceedings of both houses in 1741 when an attack was launched against Walpole's government. "According to our constitution," said Samuel Sandys, who led the attack in the Commons, "we can have no sole and prime minister . . . every . . . officer has his own proper department; and no officer ought to meddle in the affairs belonging to the department of another." The minority in the House of Lords which drew up a protest was even more forthright saying, "We are persuaded that a sole, or even a First Minister is an officer unknown to the law of Britain, and inconsistent with the Constitution of this country and destructive of liberty in any government whatsoever."

On the fall of Walpole in 1742 the further development of the office was checked in the latter half of George II's reign, and in the early part of George III's reign. Thus George Grenville (1763–65) thought that, "Prime Minister is an odious title," and Lord North (1770–82) would not countenance it. It was the younger William Pitt who consolidated the work of Walpole and by his long tenure of power (1783–1801, 1804–06) accustomed the nation to the office, if not to the name. The extent of his achievement can be measured by the terms of his famous interview with Henry Dundas, 1st Viscount Melville, in 1803. Pitt "stated . . . that there should be an avowed and real minister possessing the chief weight in the council, and the principal place in the confidence of the king. In that respect there can be no rivalry or division of power. That power must rest in the person generally called the first minister, and that minister ought, he thinks, to be the person at the head of the finances." Nevertheless, old prejudices die hard. In 1829 it could still be said in Parliament that "nothing could be more mischievous or unconstitutional than to recognize by act of parliament the existence of such

an office." Such recognition was not granted until 1905, when by royal warrant the prime minister became known to the law merely as one who had precedence next after the archbishop of York.

The prime minister is appointed by the sovereign. "I offered," said Sir Robert Peel on his resignation of office, "no opinion as to the choice of a successor. That is almost the only act which is the personal act of the sovereign." And, as late as 1894, Queen Victoria could call the earl of Rosebery without consulting the retiring prime minister, William Gladstone, or the wishes of the parliamentary majority. Nevertheless, the crown's freedom of choice became increasingly circumscribed. The "economic" reforms of the marquess of Rockingham's administration (1782), by reducing the royal patronage, made it less easy for the crown to put ready-made majorities at the disposal of whatever minister it might choose, and the Reform Bills of the 19th century made the ministry dependent on Parliament and the electorate instead of on the royal favour. The prime minister is now normally the acknowledged head of the party commanding a majority in the House of Commons, and it is only on occasions when no party commands an absolute majority of the House, or when the majority party has no acknowledged head, that there is room for the exercise of the royal discretion.

An official residence, 10 Downing Street, is assigned to the prime minister and he also has the use of Chequers, a country mansion in Buckinghamshire. But there is no salary attached to the office. The prime minister merely draws the emoluments of whatever other office he may happen to hold. At the close of the 17th century the lord treasurer was already regarded as the most important government official, and the leading minister has normally held the office of first commissioner, or first lord, and it is by virtue of that office that he draws his present salary of £10,000 a year as laid down in the Ministers of the Crown Act (1937). But the earl of Chatham was lord privy seal; the marquess of Salisbury successively foreign secretary and lord privy seal; and Winston Churchill simultaneously first lord of the Treasury and minister of defense. It used to be normal for the prime minister to be the leader of the House of Commons, but increasingly in the 20th century prime ministers have found this burden excessive and transferred it to other shoulders.

In the 18th century, when cabinets were composed almost exclusively of peers, the leading minister, curiously enough, was recruited most of the time from the Commons; in the 19th century, when Commons came to form the bulk of the Cabinet, the prime minister was, more often than not, a peer. But with the expansion of the franchise and the reduction in the powers of the Lords (notably by the Parliament Act of 1911) it became increasingly difficult for a peer to exercise the premiership effectively from the House of Lords. No peer has been prime minister since Lord Salisbury resigned in 1902 and when Lord Curzon was passed over for the premiership in favour of Stanley Baldwin in 1923 this was generally regarded as a decisive demonstration of the need for a prime minister to be in the Commons. In 1963 when Lord Home was appointed prime minister, he resigned his peerage and was subsequently elected to the House of Commons.

The prime minister, with the sovereign's consent, appoints his fellow ministers to their respective posts. Originally, of course, the sovereign exercised an unfettered choice and even in the 19th century Queen Victoria more than once successfully opposed some ministerial appointments. Today, however, the prime minister can appoint whom he will, though of course he must have regard to political considerations, in particular the need of maintaining the confidence of the House of Commons. Finally, since 1918, it is the prime minister individually and not his Cabinet collectively who advises the sovereign to dissolve Parliament. In the event of a Cabinet dispute this places him in a very strong position, especially since with it is coupled the right of dismissal. However, the responsibility of the Cabinet to the prime minister belongs properly to the history of the Cabinet (*q.v.*).

The history of the second quarter of the 20th century, with its recurring crises, showed that the position held by the prime minister was still subject to development and was still dependent upon personal factors. In the financial crisis of 1931 George V exer-

cised his prerogative of choosing as leader of a "national" coalition James Ramsay MacDonald, the leader of a minor section in a defeated and divided Labour Party, not Stanley Baldwin, who was leader of the Conservatives, the largest party. For a time the office of prime minister was inevitably weakened. The crisis caused by the abdication of Edward VIII (1936), on the other hand, temporarily gave to the prime minister (Baldwin) the sovereign's prerogative of acting as liaison between the prime ministers of the dominions. The much greater crisis of 1940 produced further drastic changes. When Churchill was appointed he was not the acknowledged leader of any party. The stresses of war and the personal ascendancy of Churchill increased the importance and prestige of the prime minister. He assumed a responsibility for the armed forces and for their direction almost equivalent to the responsibility held by the president of the United States. He became more of an ambassador-at-large than any predecessor. Radio broadcasting put him into an intimate relationship with the whole country, quite without precedent and far transcending his indirect relationship with the electorate through Parliament. The prime minister's position was thus, on the whole, strengthened vis-à-vis his Cabinet colleagues, vis-à-vis Parliament and perhaps vis-à-vis the electorate. The return to peace in 1945 reduced the occasion for such exercise of power, and prime ministers after Churchill were not such commanding figures. The Suez crisis of 1956, however, saw Sir Anthony Eden act with a minimum of Cabinet consultation and was a reminder that, if he has party support, a prime minister can dominate his Cabinet colleagues.

A modern prime minister commands a significantly increased volume of patronage: about 100 ministerial posts alone are his exclusive appointment. In the 19th century Gladstone was thought to be abnormal in having a policy of his own, and most prime ministers before 1914 were, at best, no more than strong chairmen in their Cabinets. Later prime ministers were in this respect far more Gladstonian than Gladstone. This met with criticism, but, by concentrating its attacks upon the central figure, the opposition unwittingly did much to consolidate the prime minister's dominance. Although in 1945 the electorate appeared to be offered a choice between a party program (Labour's) and a party leader (Churchill) and appeared to prefer the program to the personality, in general 20th-century elections were increasingly a choice between rival candidates for the premiership. The use of radio and television contributed powerfully to this trend, as did the whole tendency toward the centralization of politics. (For lists of the prime ministers see MINISTRY, GOVERNMENT.)

Commonwealth Countries.—The British prime minister has become the model for prime ministers in the member states of the Commonwealth and the evolution of the office in the dominions has proceeded along lines similar to those in Great Britain. Thus in Canada it developed *pari passu* with the gradual development of responsible government, so that there is room for dispute about the stage at which a prime minister clearly emerged; though Sir Allan Napier McNab (1854–56) is often regarded as the first, the office was not clearly established until after federation, when John Alexander Macdonald held it from 1867 to 1873. In New Zealand, Henry Sewell, who formed the first responsible ministry in 1856, is sometimes regarded as the earliest prime minister, though his tenure of office was merely 6 days. In Australia the granting of responsible government to the states in the 1850s produced the first crop of initially weak and short-lived ministries, but by the time of federation in 1900 the office of prime minister was fully developed and in 1901 Edmund Barton became the first prime minister of the new Commonwealth of Australia. (The Australians now confine the title "prime minister" to the chief minister of their Commonwealth Cabinets, using the term "premier" for the chief minister of each state.) In South Africa the granting of responsible government to the Cape Colony in 1872 led to the premiership of John Charles Molteno; in Natal, similarly, in 1893 Sir John Robinson became prime minister; the Union of South Africa was established in 1910 with Louis Botha as its first prime minister. In India, elections held in 1937 under the Government of India Act (1935) resulted in the establishment of cabinet government under prime ministers in the 11 provinces and when in

1947 full autonomy was granted Jawaharlal Nehru became first premier of India and Liaquat Ali Khan of Pakistan. Similar developments occurred in other parts of the Commonwealth as they attained self-government.

The constitutional position of these prime ministers is much the same in all Commonwealth countries. In most the tendency has been toward the evolution of strong premierships, and certain figures like William Lyon MacKenzie King in Canada, Nehru in India and Sir Robert Menzies in Australia are notable for long tenure of office. Australia is peculiar in having established a prime minister's department, but this is, in effect, a general Cabinet secretariat. The Australian Labor Party has also adopted a provision unknown elsewhere obliging its leader, on becoming prime minister, to accept for his cabinet those members elected by the party caucus and also to submit his program for caucus approval.

Ireland.—The compelling effect of the British concept of the prime minister's office is well illustrated by its history in Ireland. The constitution of the Irish Free State in 1922 specifically aimed at reducing the prime minister's power. Serving under a popularly elected president, he was to seek the approval of the *dáil éireann* (House of Commons) for the choice of his colleagues, was denied full powers of dissolution in the event of defeat, and was given no option but to resign. So strong, however, were the habits borrowed from Whitehall and Westminster, that these provisions became a dead letter even before the 1937 constitution formally modified them and at the same time, in entitling the prime minister *Taoiseach* (leader), implicitly recognized his command.

France.—Imported into countries in the rest of the world with different traditions of executive leadership, the office of prime minister, or premier, has undergone various modifications. As might be expected, it is in the surviving constitutional monarchies, like those in Scandinavia and the Low Countries, that the British norm is most closely approximated. France, oscillating between the "Napoleonic" and the parliamentary elements in its tradition, has varied the powers of the premier (*président du conseil des ministres*) under its various constitutions. The restoration of Louis XVIII in 1814 brought a measure of representative government and with it the first premiers under a parliamentary system, though their effective powers depended on the monarch they served. Men such as Casimir Périer, Louis Adolphe Thiers, Louis Molé, and François Guizot were, nonetheless, considerable figures. The Second Empire (1852–70), however, represented virtually a return to the sort of uneasy balance of powers between monarch, ministers, and Parliament that had existed in Britain in the 17th century.

The Third Republic (1870–1940) settled down into a system under which a president filled the role of a constitutional monarch and the premier was supposed to discharge the functions of his British counterpart. In fact, with a few notable exceptions, such as Georges Clemenceau, premiers were weak executives, and their terms of office unstable and short-lived (there were more than 50 in the 70 years of the Republic). This was due to the lack of strong parties and the consequent dependence of each ministry upon fluctuating coalitions in the Chamber of Deputies. The premier had no power of dissolution, and no other effective method of disciplining the legislature. The Fourth Republic (1946–58), though it slightly strengthened the premier's hands in forming a government and gave him a very limited power of dissolution, did nothing to increase the stability of governments. The Fifth Republic (1958–) represented a swing in the "Napoleonic" direction, strengthening the president, weakening Parliament and placing the premier in an ambiguous position between the two. A "separation of powers" removes him from membership of the National Assembly, though he can appear and speak there; Parliament, dissolvable and restricted in its powers, is less able to control him, though he still needs a majority there. But many of his executive powers, especially over foreign affairs, have passed to the president, whose pale shadow the premier appears to have become. (For lists of premiers see FRANCE: History.)

Italy.—The European country most closely resembling France in the role of its premier is Italy. Conte Camillo di Cavour became the first Italian premier, but he had been preceded in Piedmont by the marchese D'Azeglio, the first premier under the

Piedmontese constitution of 1848. In fact, however, the political backwardness of the country and the fluidity of party groupings in Parliament made premiers more dependent on royal favour than on any other single factor. They were sometimes weak, sometimes dictatorial, and their terms of office always brief. Between 1860 and the coming of Fascism in 1922, Italy had 38 premiers. The new constitution of 1947, however, ushered in a system which, while generally similar to that of the French Fourth Republic, made possible more stable ministries and proportionately stronger premiers. Alcide de Gasperi (1945–53) was an especially notable figure; his successors were less impressive and the presidency tended to grow in power at the expense of the premiership.

Germany.—Germany gives its prime minister the title of chancellor. Under the Empire (1871–1918), even though the chancellor was endowed with explicitly superior powers vis-à-vis the other ministers, he was always (even Otto von Bismarck) dependent on the kaiser. In the Weimar Republic (1919–33) he was a greatly weakened figure; Cabinet decisions were by majority vote and he had to allocate portfolios at the direction of the parties which made up his coalition. The constitution of the German Federal Republic in 1949 explicitly guarded against such weakness by stipulating that the *Bundestag* might "express its lack of confidence in the federal chancellor only by electing a successor with the majority of its members." This, together with the strong personality of the first chancellor, Konrad Adenauer (1949–63), gave the office a strong start. Adenauer interpreted very literally the constitutional clause which asserts that "the federal chancellor determines, and is responsible for, general policy." Creating two "state-secretaries," one for foreign affairs and the other as a kind of chief of staff, both responsible to him personally, he treated his Cabinet as a mere board of experts, discouraging any spirit of collective responsibility. Roughly similar conditions apply to the equivalent office of *minister-president* in the *Land* governments.

Japan.—In Japan, the other state most notably "democratized" after World War II, a somewhat similar situation prevailed. There, by the constitution, the prime minister "exercises control and supervision" over the whole of the executive and his countersignature is required for all laws and Cabinet orders. The ministers are thus very largely merely extensions of his authority. The legislature selects the prime minister from among its own members and normally chooses the leader of the majority party. If the Cabinet loses the confidence of the lower house of the legislature the Cabinet must either resign or dissolve the house.

U.S.S.R.—The post of chairman of the Council of Ministers in the Soviet Union is often identified in English as that of prime minister, though there is little similarity beyond the title. The Council of Ministers is the highest executive organ in the Soviet Union and is answerable only to the Supreme Soviet or to the Presidium. See UNION OF SOVIET SOCIALIST REPUBLICS.

BIBLIOGRAPHY.—Sir William Ivor Jennings, *Cabinet Government*, 3rd ed. (1959), and John P. Mackintosh, *The British Cabinet* (1962). For the Commonwealth no adequate comparative treatment exists later than A. B. Keith, *Responsible Government in the Dominions*, 2 vol., 2nd ed. (1928). (H. G. N.)

PRIME NUMBER, a positive integer (whole number) greater than 1 that cannot be expressed as the product of two positive integers neither of which is 1. The first few prime numbers are 2, 3, 5, 7, 11. Every positive integer greater than 1 can be expressed as a product of one or more prime numbers; for example, $2 = 2$, $3 = 3$, $4 = 2 \cdot 2$, $5 = 5$, $6 = 2 \cdot 3$, $7 = 7$, $8 = 2 \cdot 2 \cdot 2$, $9 = 3 \cdot 3$, $10 = 2 \cdot 5$, $11 = 11$, $12 = 2 \cdot 2 \cdot 3$.

In symbols, if p is a prime number and if a and b are positive integers such that $ab = p$, then either $a = p$ or $b = p$. Euclid (*q.v.*, fl. 300 B.C.) proved the stronger assertion (*Elements*, book vii, proposition 30) that if a and b are positive integers such that ab is a multiple of the prime number p , then either a is a multiple of p , or b is a multiple of p . From this follows the so-called fundamental theorem of arithmetic: every positive integer greater than 1 can be expressed as a product of prime numbers in one way only (apart from rearrangement of factors).

Composite Numbers.—A positive integer greater than 1 which is not a prime is said to be a composite number. If n is a composite number, it must be a multiple of some prime number not exceeding

\sqrt{n} , since the product of two or more numbers greater than \sqrt{n} must be greater than n . Thus to show that a given positive integer n is a prime number, it need only be shown that it is not a multiple of any positive integer between 2 and \sqrt{n} inclusive.

Sieve of Eratosthenes.—The prime numbers not exceeding any positive integer N can be found by a process known as the sieve of Eratosthenes (*q.v.*): write the positive integers between 2 and N inclusive in numerical order; the first integer 2 is a prime number. Now cross out all the multiples of 2 other than 2 itself; that is, cross out 4 and every second integer, 6, 8, 10, and so on. The smallest integer remaining is 3, the next prime number. Now cross out all the multiples of 3 other than 3 itself; that is, beginning with 6, cross out every third integer. The smallest integer remaining after the deletion of the multiples of 2 and the multiples of 3 is 5, the next prime. Now cross out all the multiples of 5 other than 5 itself; that is, beginning with 10, cross out every fifth integer. The smallest integer remaining after the deletion of the multiples of 2, 3 and 5 is the next prime after 5, namely 7. Continue this sieving process until all the multiples of all primes not exceeding \sqrt{N} , other than those primes themselves, have been crossed out. The numbers not crossed out at least once will comprise the set of all primes not exceeding N .

Infinity of Primes.—Euclid (*Elements*, book ix, proposition 20) proved as follows that there are infinitely many prime numbers. Let P denote the product of all numbers in some finite list of prime numbers. Then $P + 1$ is not a multiple of any prime in the list (*i.e.*, division of $P + 1$ by any one of these primes leaves a remainder of 1). Hence, each prime factor of $P + 1$ is a prime number not occurring in the list (meaning just $P + 1$ itself if it is a prime number). Thus, no matter how extensive a finite set of primes is, there must be primes it does not contain.

Dirichlet's Theorem.—No polynomial (*q.v.*) expression in n can take prime values for all positive integral values of n . For example, $n^2 - n + 41$ is a multiple of 43 whenever n is 1 less or 2 greater than a multiple of 43, and $6n + 5$ is a multiple of 11 whenever n is 1 greater than a multiple of 11. However, in 1837 P. G. L. Dirichlet (*q.v.*) proved the theorem that if c and d are positive integers with no prime factors in common, then the expression $cn + d$ takes prime values for infinitely many positive integral values of n . Some of the simpler cases of Dirichlet's theorem can be proved by an elaboration of the argument Euclid used to prove the existence of infinitely many primes. For example, to show that there are infinitely many primes of the form $4n + 1$, merely replace $P + 1$ with $4P^2 + 1$ in Euclid's proof. However, the general proof of Dirichlet's theorem, although simplified since his time, is not easy. No analogous result is known for polynomials of higher degree. For example, it is not known if there are infinitely many primes of the form $n^2 - n + 41$.

Prime-Number Theorem.—The n th prime number is usually denoted by p_n , and the number of primes not exceeding the positive integer N is usually denoted by $\pi(N)$. It is possible to give artificial formulas for p_n and for $\pi(N)$ that amount to giving detailed instructions for the sieve of Eratosthenes, but in neither case is a really simple or natural formula known or to be expected.

The so-called prime-number theorem tells approximately how large p_n and $\pi(N)$ are for given values of n or N . It was conjectured by A. M. Legendre and C. F. Gauss early in the 19th century, but was first proved in 1896 by J. S. Hadamard and by C. J. de la Vallée Poussin, working independently. The prime-number theorem asserts that p_n is roughly $n \ln n$ when n is large, and that $\pi(N)$ is roughly $N/\ln N$ when N is large. Here \ln denotes the natural or Napierian logarithm of n , which is $2.302585093 \dots$ times the logarithm of n to the base 10 (*see* LOGARITHMS). More precisely, the ratio $p_n/(n \ln n)$ approaches 1 as a limit when n becomes large, and the ratio $\pi(N)/(N/\ln N)$ approaches 1 as a limit when N becomes large. An even better approximation to $\pi(N)$ than $N/\ln N$ is provided by the definite integral $\int_2^N (\ln t)^{-1} dt$, which is essentially the same as the sum of the reciprocals of the natural logarithms of all the positive integers between 2 and N inclusive. While the logical structure of the proof of the prime-number theorem was greatly clarified after 1896, the proof was still difficult in the 1960s.

By counting the number of integers crossed out in performing the sieve of Eratosthenes, it is possible to find the exact number of primes not exceeding a given number N , *i.e.*, $\pi(N)$, without listing all the primes up to N individually. This is an extensive calculation if N is large, but it is much less ambitious than is listing all primes up to N . The following table gives the results of some calculations of this nature along with corresponding approximations by the prime-number theorem.

N	Integer nearest $N/\ln N$	$\pi(N)$	Integer nearest $\int_2^N (\ln t)^{-1} dt$
10	4	4	5
100	22	25	29
1,000	145	168	177
10,000	1,086	1,229	1,245
100,000	8,686	9,592	9,629
1,000,000	72,382	78,498	78,627
10,000,000	620,421	664,379	664,917
100,000,000	5,428,681	5,761,455	5,762,208
1,000,000,000	48,254,942	50,847,534	50,849,234
10,000,000,000	434,294,482	455,052,511	455,053,614

Distribution of Primes.—Although the prime-number theorem gives a good over-all picture, many questions about how the primes are distributed remain unanswered. For example, in the 1960s it was still not known just how well $\int_2^N (\ln t)^{-1} dt$ approximates $\pi(N)$. Also, relatively little was known about the behaviour of the gaps between consecutive primes. It is clear that arbitrarily large gaps occur, but only crude estimates were known of how far to go in the sequence of prime numbers to find a gap of given size. Whether the gap 2 occurs infinitely often was likewise unknown. *See also* NUMBERS, THEORY OF.

Ayoub, *An Introduction to the Analytic Theory of Numbers* (1963). (P. T. B.)

PRIMITIVE ART is that made and used by members of primitive societies (*see* ART). This discussion deals largely with the visual art of primitive societies. Such art is generally functional to the extent that primitive sculpture, painting, and decoration are usually of religious and social importance; while the meanings and uses of primitive art objects are not always known, it is better to assume them all to be useful, rather than as made for art's sake. The use for which the artist intends his work delineates so-called fine (pure, serious) art from minor (*e.g.*, applied, decorative, industrial, commercial) art. Yet many objects considered to be fine art in modern cultures of European origin were made and first used as religious paraphernalia. An artifact is recognizable as art by the aesthetic organization of its visible form. Order, consistency, rhythm, harmony, and balance of lines, shapes, masses, colours, light values, and textures serve to identify artistic quality in an item of material culture.

Art is one way to present symbols for use in human social life, fixing in visible and enduring form otherwise intangible and transient images, ideas, and events. Barring purposeful destruction, persistence of visual art is limited only by the durability of its materials. But by contrast with everyday experience, the aesthetic characteristics help fix the symbols in human awareness and memory at the moment of presentation. Ceremonial art is a conscious and determined effort to make important symbols visible and permanent. Since aesthetic quality is common to all art, the word primitive refers only to the nature of the society in which the work originates. But authorities may disagree in applying the term. Many (as does this section) have termed primitive those small, isolated, homogeneous, and intimate societies where literacy is absent, where there is informal social control, and where there is strong group solidarity.

On the other hand, if primitive is taken to mean original or first, difficulty arises in applying the term either to contemporary

societies or to those of the recent past. The art of the very first human society probably never will be known; however, the term primitive can be used to indicate the relative primacy of a society and its art. The oldest surviving art known is that of the Upper Paleolithic in Europe; but this should not be called the dawn of art, since earlier man may have produced art in Europe, and in other parts of the world as well. The arts of precivilized and non-civilized societies may both be called primitive. The distinction of specific primitive societies hinges in part on judging the origin and rise of civilizations. At any rate, the following distinctions between so-called primitive and civilized peoples should be regarded only as provisional.

In Europe and Asia primitive societies existed prior to the development of civilizations; however, because these civilizations have flourished longer and more widely than those elsewhere, very few primitive societies have persisted. These are the Siberian Eskimo, the Ainu of Japan, and some peoples marginal to the Chinese and Indian civilizations. In Oceania the Indonesian civilization may be thought of as having derived from Asia; however, the aboriginal inhabitants of Malaysia, Australia, Melanesia, Micronesia, and Polynesia fall into a noncivilized (primitive) category. The aboriginal inhabitants of the Americas were members of primitive societies, some of which developed into civilized societies in Andean South America and in Mesoamerica (Valley of Mexico and the Mayan area). Among the intermediate peoples in western Mexico, the Circum-Caribbean, and northwestern South America, evidence in the 1960s failed to clearly separate primitive from nonprimitive societies. Egypt and North Africa are related to Eurasian civilization; but south of the Sahara many aboriginally primitive societies persist. In West Africa there were several indigenous civilized states (Ashanti, Dahomey, Oyo, and Benin); yet their art is often grouped as primitive.

The small size and informal social control of many societies labeled as primitive tend to limit the size of art objects produced; isolation of such societies limits the importation of raw materials. Relatively simple division of labour (by age and sex) tends to limit specialization of artists. Primitive artists, under the necessity of farming, collecting, or hunting for a living, tend to function part-time. The special skills of primitive artists thus tend to have less time to develop than do those of full-time artists in civilized society. This may be why although much primitive art seems relatively vital it sometimes seems crude in technique, compared to some very delicately rendered art objects from civilized societies.

I. PREHISTORIC EUROPE

The discovery of Ice Age (Pleistocene) art must be linked strictly with E. A. I. H. Lartet (*q.v.*), although a few years earlier the geologist P. A. Brouillet had discovered perforated staffs of bone at the Grotte de Chaffaud near Savigné, Vienne, France, and an Englishman, E. Mayor, had discovered pieces of worked bone near Geneva, Switz. In France, Lartet explored (1862) the caves of Espéluques near Lourdes and carried out excavations in the Les Eyzies district, Dordogne, bringing to light a large number of engraved and sculptured bones and, in the Chaffaud cave, a number of drawings on the cave walls. The case made by Lartet and H. Christy for the high antiquity of these works was strengthened by the discovery in the Grotte de la Vache, in an undisturbed Ice Age deposit, of engraved mammoth bone with a representation of this extinct animal.

Between 1860 and 1880, in southern France and on its southeastern frontier, burials of Upper Paleolithic man were found at Laugerie-Basse, in the caves at Grimaldi near Menton, and at Cro-Magnon itself, revealing skeletons, shell ornaments, and flint tools above strata of accumulated Ice-Age artifacts (*see CRO-MAGNON MAN*).

In 1868 in the province of Santander, Spain, the first of the

big painted caves (*see ALTAMIRA CAVE*) was found. It seemed to have been closed by a fall of rock at the end of the Ice Age; bone implements lay immediately below the debris. Other Paleolithic paintings were found in France: in Chabot cave, Gard, in 1878 by L. Chiron, and in the cave at Pair-non-Pair, Gironde, in 1883. The Pair-non-Pair pictures were entirely covered by late Aurignacian deposits that permitted accurate assignment. Other caves were opened in rapid succession: Marsoulas, Pyrenees (1897), and Font-de-Gaume and Les Combarelles in the Dordogne. French discoveries in cave painting and minor art were made in 1902 by H. E. P. Breuil (*q.v.*), and in 1912 by Count H. Béguen. In 1923 N. Casteret discovered Montespan cave and in 1932 that at Labastide, both in the Pyrenees. The most important discovery since has been the Lascaux cave, Dordogne, with excellent frescoes, in 1940.

Meanwhile prehistoric paintings had been discovered in caves in southeast Spain from Lérida to Cádiz, but little was found to help date them.

A number of smaller works of prehistoric art have been found in Germany and the Low Countries. Eastern Europe and the U.S.S.R. are also rich in minor works, few of which approach the high artistic quality of the French finds and some of the Swiss carvings. Britain has produced a few crude engravings on bone, but no evidence of cave art.

Paleolithic Art.—Carved and Incised Objects.—Although human beings are rarely represented in the cave art of western Europe, the earliest plastic figures represent mature steatopygous females with pendulant breasts. These figurines show remarkable consistency in style over their total distribution from France to southern U.S.S.R., are carved in bone or schist, once coloured, and are known as Venuses. The earliest examples come from middle Aurignacian contexts, but those from later Aurignacian-Perigordian period are of higher quality. About 130 examples are known, many from the encampment sites of mammoth hunters at Gagarino, Ukraine, U.S.S.R., where special niches to house them were built into the hut walls. One of the most noted examples comes from Willendorf, Aus., while another, the head of such a figure with retted hair and beautifully marked facial features, is the famous Venus from Brassempouy, Landes, France. In the Ukraine and in Moravia, Czech., these figurines become highly schematized, reduced often to pegs of ivory or bone with highly developed buttocks and breasts. Few bodily features are marked, although some examples have extremely thin arms folded over the chest. Moravian examples have incised geometric-spiral designs on the back and buttocks which might represent tattooing. Male statuettes are much rarer and are artistically inferior, but a male head from Dolní Věstonice in Moravia has its features realistically carved.

Larger-scale sculpture is almost entirely confined to France, probably arising from natural rock forms of suggestive shape. A parallel to the Aurignacian Venus figurines is the low relief from Laussel, Dordogne, of a steatopygous female figure holding a "cornucopia." Similar Perigordian reliefs were carved in partly exposed rock shelters at Cap Blanc, Dordogne, and some of ibexes and wild boar were found on the Roc-de-Sers, Charente. High relief animal sculptures at Angles-sur-Anglin, Vienne, are Magdalenian. The only piece of sculpture in the round is the head of a musk ox from Laugerie-Haute, Dordogne, 9 in. high, but Magdalenian sculptures in clay of a bear from the Montespan cave, Garonne, and copulating bison from the Tuc d'Audoubert, Ariège, approach the roundness of sculpture. Some of the stone reliefs are the only art attributable to the ill-defined Solutrean period (*see ARCHAEOLOGY*).

In the Magdalenian period miniature carving of animals predominated particularly in western Europe. Archaeologically stratified ivory carvings have come from Stetten ob Lontal, Wurttemberg, Ger. (wild horse, panther, mammoth), and from late Aurignacian mammoth-hunting stations in Moravia, where clay models accompanied ivory (mammoth, bear, wild horse, reindeer owl). In French sites miniature sculptures come mostly from Magdalenian strata. These pieces, particularly those of horse and bison heads, surpass anything in eastern Europe. Particularly

Clay funerary urn, Kansu, Yangshao period. 11 in. high

Bronze *dōtaku*, Japan. About 28 in. high

Female figurine, possibly a fertility idol, late Jōmon period, Japan. 10 in. high

PREHISTORIC ASIAN ART

Group of clay tomb figurines (*haniwa*) from Kantō, Japan. Seated woman (foreground), possibly a shaman, is 27 in. high

Cave painting showing bulls, horses, and deer; Lascaux, Dordogne, France. Photograph covers a span of about

Ivory horse; Espéluques near Lourdes, France. About 3 in. (actual size)

Views of female head carved in ivory; Brassempouy, Landes, France. About 1¼ in. high

Horse's head carved in reindeer antler; Le Mas d'Azil, Ariège, France. About 2 3/8 in. from neck to nose

Bison carved in reindeer antler; Vache de la Madeleine, Dordogne, France. Length 4 1/8 in.

Carved relief of a female holding a bison horn; Laussel, Dordogne, France. 15 3/4 in. high

PREHISTORIC EUROPEAN ART

Bison painted over a protuberance on cave roof; Altamira, Spain. About 6 ft. long

North American artifacts. (Left) Pueblo Indian kachina figure, wooden body dressed in cloth and feathers. About 13 in. (Above) Prehistoric stone pipe, Eastern Woodlands. 3½ in. high. (Right) 20th-century Eskimo carvings, done in the primitive manner. The hunter, about 10 in. high, is stone; the seal is ivory

ART OF THE NEW WORLD

Painted clay effigy vessel, possibly representing a warrior; Colima, Mexico. 14¾ in.

Gold Aztec delfy pendant; Oaxaca, Mexico. 4 in. high.

Chavin ray pot with characteristic puma-head motif; Peru. About 11 in.

Painted clay bowl with bizarre monster design; Panama. Diameter about 11 in.

Maya stela; Copán, Honduras

Tiahuanaco featherwork; Peru

Mochica gold earplugs inlaid with turquoise; Peru. Diameter 4 in.

Detail of embroidered Paracas mantle; Peru

Olmec basalt head; Mexico. 8 ft. high

Cult house with carved and painted wood *Malanggan* figures representing mythological scenes, ancestors, totem birds, and fish; New Ireland. House is about 8 ft. high

ART OF OCEANIA

Bird-shaped stone pestle, one of the few Oceanic artifacts that can be dated to prehistoric times; New Guinea. 13½ in.

Kukailimoku, war-god of wicker framework covered with netting and feathers, eyes of shell, mouth rimmed with dog's teeth; Hawaii. 32 in.

Kukailimoku in wood; Hawaii. 30¼ in

Wood image of the god Tangaroa, creating man and other gods shown sprouting from his body; Rurutu, Austral Islands. 44 in.

X-ray style painting of kangaroos, earth colours on eucalyptus bark; Arnhem Land, Australia. 40 3/4 in. high

Protective idol, blackened wood inlaid with mother-of-pearl, from prow of a war canoe; New Georgia, Solomon Islands. 7 in. high

Carved wood lintel from Maori council house door; New Zealand. About 30 in. long

Carved wooden god; Cook Islands. 54 in.

Thirteenth-century life terra-cotta commemorative head; Nigeria. Life size

Gold Ashanti turtle pendant, Ghana.
3¾ in. long

Gold Bwa pendant; Ivory Cord.
About 3 in. long

Wood Ibibio marionette; Niger. 5¾ in.

AFRICAN ART

Painted wood Yoruba Shango cult figure; Nigeria.
28½ in.

Painted wood Kurumba antelope headress; Upper
Volta. 42¾ in.

Wood Yoruba horse and rider; Nigeria. About
30 in.

fine are a horse's head of reindeer antler from Le Mas d'Azil, Ariège, and a standing horse in ivory from Lourdes. Some have harpoons engraved upon them and must have been used as hunting talismans; some of the best examples are carved on throwing sticks and other hunting implements.

In this category are the carved finials of spear-throwers of Le Mas d'Azil in the form of a chamois or a black cock, handles like one carved in the form of two crouching deer from Bruniquel Tarn-et-Garonne, and another in the form of a single reindeer from Laugerie-Basse. Perforated staves of ivory are sometimes carved with animal terminals; although known as *bâtons de commandement*, they were probably used as arrow-straighteners. These are often covered with designs of deer, horses, birds, and fish.

The vast majority of Magdalenian finds are isolated engravings on bone, flat tines of antler, small slabs of stone or flat pebbles, executed sometimes with surety, sometimes as though they were practice pieces. Notable are Dordogne examples of hairy bison's heads from Limeuil and Laugerie-Basse on bone and small limestone blocks. From Teyjat come experiments in group drawing: a herd of reindeer with only the outer animals drawn in detail, the herd effect achieved by central multiplication of legs and antlers. A herd of galloping horses is treated less summarily. A more detailed style is seen in antler engravings from Lorthet in the Pyrenees where, on a spear-thrower, reindeer are shown swimming. The hooves and body hairs are drawn with precision, as are details of salmon swimming between the beasts' feet.

Bone engravings of Pyrenean quality are not common elsewhere in Europe, but from the Pekárna cave in Moravia comes a masterly representation of bison in combat. Here too were found perforated staves parallel to the French type, and bone pieces engraved with horse, bison, and chamois. Outline engravings of mammoths have been found at Kostienki I and Maltà, near Lake Baikal, Siberia. In these minor and applied arts of the Magdalenian period no interest is shown in scenic background, or the human figure; the few examples of what appear to be human beings, including an engraved bone from Pin Hole cave, Derbyshire, Eng., are badly executed and difficult to discern. These minor pieces, though scarcely surpassed in treatment and skill, are greatly surpassed in scale by the engravings and paintings in caves.

Cave Engravings and Paintings.—Geographical limitations confine cave art largely to southwest France and northeast Spain, the so-called Franco-Cantabrian province, but isolated finds come from southern Italy, southern Germany, and southern U.S.S.R. In the absence of firm chronology, it is difficult to reconstruct stylistic development, even in France. Cave decoration is either made with stone gravers or with masses of liquid paint. While massive sculpture is usually placed in open rock shelters, paintings and engravings are usually hidden in deep recesses of caves where clay

modeling was also practised. Breuil's lifelong study outlined the evolution of cave art from simple Aurignacian line engraving to late Magdalenian polychrome painting. Incised on hard rock surfaces, painted, or drawn in wet clay with a finger, the lines were originally of uniform thickness, later revised and modulated. The detailed drawing of pelt, muscles, and other anatomy tends to be zonal.

Painting and engraving often appear together in caves and probably came into use simultaneously. Distinctions in style suggest that painters and engravers practised separate crafts. Only one known cave is decorated exclusively with engraved designs: Les Combarelles, Dordogne, has thousands of superimposed engravings from late

Aurignacian through middle Magdalenian, suggesting that this cave was the centre of a hunting cult. Bison and reindeer are the main repertoire, but grotesque humans with parts of other animals are perhaps decoys or hunting magicians. Some of the engraved animals are lively, others stiff; chronological distinctions between these styles cannot be accurately made. From stratified caves, however, it appears that Aurignacian style was close-contoured and stiff, and lacked the three-dimensional qualities of the later period. At Altamira, Teyjat (Dordogne), and Font-de-Gaume, engravings accompany Magdalenian wall paintings; it is possible to appreciate the plastic qualities of Magdalenian engraving and efforts to represent dimension, although the positioning of feet (often completely omitted) is embarrassing. Action is depicted at Font-de-Gaume, where a pregnant lioness is engraved ready to spring and horses canter in file. At Altamira leaping hinds and baying stags have lifelike qualities, antlers drawn in fine perspective. These epitomize the extremely flowing style of Magdalenian engraving, seen in plodding mammoths at Font-de-Gaume and some of the bears depicted at Les Combarelles.

At Lascaux, in a ramified cave of passages and chambers on various levels, the best-preserved traditions of later Aurignacian art survive; the Pech-Merle cave, Cabrerets, should be associated with it. Paintings in both caves are executed in thick black outline little refined. The bodies of some of the animals are washed in with red or brown paint, shading off toward the underparts. Horses are painted in solid black silhouette, but some horses, bison and aurochs (*q.v.*) in both caves are painted with an over-all dot pattern. Friezes of horses and bulls traverse the lower edge of the arched roof, while the upper portions are left for depicting larger animals. Although the paintings are superimposed, at Lascaux there seems to have been a consistent attempt to decorate the roof in an orderly fashion. In other caves animals are painted without significant relationships.

Altamira cave remains preeminent in Magdalenian style. The natural bulges of the 7-ft.-high rock roof were painted with standing and squatting bison, thickly outlined in black and filled in with red, producing an effect of unparalleled beauty and realism. About 20 of them cover a distance of about 15 yd. The rock formation was used to give a round effect in the body; the legs were painted from underneath (the alternative in the visual dilemma was to paint the legs from the side) giving the animals a slightly concave appearance countered by the rock surface. Font-de-Gaume cave closely parallels the painted-in technique of Altamira and indeed, in parts, probably represents an earlier late-Aurignacian style, but unfortunately it is badly preserved. The Niaux caves, Ariège, belong to the same black-outline tradition but do not have painted fillings. However, the outlines, painted with thick strokes and adjusted with thin, are more carefully drawn than elsewhere and

the perspective of the feet of bison and wild horse is more successfully achieved.

Besides introducing painting as a pictorial technique the primitive art of the Paleolithic begins the expressional and magical use of colour. Black, red, brown, and a dull yellow were chiefly used. Besides animals and anthropoid figures, areas and brush marks of colour and curiously shaped tectiforms (perhaps representing huts) were sometimes painted in, as were colour-blotched outlines of stumpy human hands. Among the pigments at Altamira and Lascaux natural oxides of iron and manganese supplied red and black; iron carbonate gave yellow; at Lascaux blue-black and dark-brown manganese oxides were found; other blacks came from soot. When finely ground these pigments were mixed with water rather than a fatty base, allowing quick application to damp rock. Pigments were stored in such hollow receptacles as bones, stones, and skulls, as at Les Cottés, Vannes. Bone mortars and pestles for grinding paints, and stone lamps for lighting dark recesses have been found. Fingertips, brushes, and daubing pads were used to apply the colour.

The purpose of this art is not clear. Executed far from normal gaze, the work was apparently done in great discomfort. That it was directed at the magical possession of favourable hunting conditions is occasionally indicated. An outline-painted mammoth in the Pindal cave, Asturias, Spain, has a red blotch indicating the position of the heart and a batch of arrows painted in front of it. Outlined bison in the Niaux cave, Pyrenees, have superimposed painted barbs pointing at the heart and midrib and blotches of red (blood?) on the body. Patchwork squares painted in front of such naturally curious animals as oxen and goats at Lascaux might represent pitfalls covered with sheets of skins. In the same cave is a scene in which a man with a broken spear is worsted by a bison. Comblike patterns painted near and on top of some animals might represent fenced enclosures to which they were to be lured. A human-shaped figure (the famous "sorcerer") wearing an antler mask in Les Trois Frères cave, Ariège, might be a decoy or a hunting magician. Hunting rites are evidenced by clay model animals, some with unmistakable signs of use as targets. Other models suggest magical increase of fertility (many painted animals are pregnant and pregnant women are occasionally engraved on bone).

Toward the end of the Magdalenian period naturalistic realism weakened in favour of formalized arrangements of horns, antlers, and fur reduced to a pattern. Schematic female figures have been found from the earlier Paleolithic in Moravia; in the west chamois and reindeer were reduced to formalistic ornaments. In western Europe art was not to achieve such heights of abstraction until the appearance of the formalized Celtic art of La Tène (q.v.).

A branch of Franco-Cantabrian art is represented at the cave of Parpalló, Valencia, where engraved bone pieces are stratified in Gravettian, Solutrean, and Magdalenian contexts; and where stones with animal paintings occur in the Solutrean. At La Pileta cave, Málaga, a peripheral Magdalenian style of painting seems to have been introduced. The animals depicted are, unlike those of France, such forest dwellers as deer, wild boar, the smaller deer and oxen, and not Ice-Age fauna; doubtless the southerly latitude is as much responsible for the difference as is the later date. The art of these two caves is possibly linked with the engraved animals in caves in Liguria, Apulia, and west Sicily and may thus belong to an ill-defined "Mediterranean" province, possibly with African connections, which continued Paleolithic artistic tradition into Mesolithic times.

Epipaleolithic (Mesolithic) Cave Art of Spain.—Another group of cave paintings, while difficult to date, can be largely attributed to the Mesolithic. Found in southeast Spain, they differ sharply in style and content from the paintings of the Franco-Cantabrian province. They incorporate an African style as seen in largely undatable paintings and rock engravings from Algeria, Tunisia, the Atlas Mountains, outer Sahara, and Bushman art in South Africa. These African examples, like those of southeast Spain, are tribal rather than individual; hunting by small family groups in Paleolithic times had been taken over by organized males of the tribe. The Spanish-Levantine painted caves, discovered mostly in the early 20th century, are grouped in Albacete (Alpera

and Minateda caves), in Teruel (Alcañiz and Tormón), in Murcia (Cogul and Yecla), in Valencia (Bicorp), in Castellón de la Plana, and in several shelters in the Valltorta gorge between Albuñol and Tirig. New paintings were brought to light at such sites as the Cueva del Polvorín, Castellón (1947). The group has one outlier, the cave of Las Batuecas between Salamanca and Cáceres.

Engravings are very rare and the absence of stratified pieces of minor art makes the dating and culture attribution of the paintings difficult, but their beginning is probably to be associated with the Upper Paleolithic Capsian industry of southeast Spain. While large-scale single animals are the rule in Franco-Cantabrian paintings, small-scale compositions of many figures were chosen by the southern Spanish artists. In most of the paintings human groups play a large part, hunting single animals with bow and arrow. All figures are painted in solid silhouette; those of animals are true to nature while those of humans are highly distorted, with elongated bodies and thick legs. The colours are chiefly red, brown, and black, largely derived from manganese and bound with blood, egg, or honey.

With tribalism came war, and many of the scenes depict lively arrow battles or mass execution of prisoners. Women, often drawn in long dresses, are shown dancing or walking with children. There is no evidence of fishing or trapping, but the dangers of the chase are vividly shown in Cueva Remigia paintings where oxen and ibexes turn on fleeing hunters. Little domestic life is shown, but a painting in the Cueva de la Araña, Valencia, depicts a woman gathering wild honey; one in the Gasulla gorge shows a spider surrounded by flies.

Paleolithic and Mesolithic Art of Northern Europe.—A third group of prehistoric art, largely from the northern limits of Europe, while again showing a generic relationship with Ice-Age art of western Europe, cannot be related to an Upper Paleolithic culture. In Finland, northern Norway (Finnmark, Nordland, Troms), central Norway (Trøndelag), and on the upper Yenisei River at Shalobolinsk in western Siberia, the custom arose of engraving scenes of hunting and magic on inaccessible slabs of rock or cliff surfaces. The linear style of arctic reindeer, elk, and bear lacks Magdalenian dimensional qualities, but is very definite and simple. The more naturalistic representations and those with perspective as seen in French Magdalenian art are found only in remotest northern Norway and Siberia. Groups of animals and disguised human decoys are sometimes shown, and great interest in the sea is evidenced by engravings of halibut and seal; and, on the White Sea coast, by boats of a type ancestral to those in Bronze-Age engravings from Scandinavia. Although hunting scenes are not shown, depiction of inner parts of animals strongly indicates that hunting-magic was the primary purpose of these drawings. For decorative purposes, superb small animal models were carved in the Danish Maglemose (Mesolithic) settlements.

Neolithic and Bronze Age Art.—The migration of Neolithic agriculturalists from the Near East to Europe and the rise of European peasant communities brought the beginnings of a folk art expressed chiefly in weaving, basketry, and pottery making. Cave art was now confined to the engraving of simple magico-religious patterns on rocks, as at Newgrange and Lochcrew in Ireland, and standing stones at Morbihan in Brittany. From Anatolia the idea of pottery painting spread into southern and eastern Europe. A variety of techniques of painting and incision are known in the chief areas of Neolithic painted pottery culture at Tripolye, U.S.S.R.; Cucuteni, Rumania; Vučedol, Yugoslavia; and the Dimini and Sesklo cultures, Greece. In all of these, designs are abstract, often spiriform; the ceramic tradition also includes figurines of women with painted or incised designs indicating elaborately embroidered clothing. Decorations on unpainted pottery from the rest of Europe show the predominant influence of basketry. In perfecting techniques of shaping and polishing stone tools the Neolithic craftsman brought to earlier Stone Age traditions a new combination of utilitarian and aesthetic feeling.

Apart from a few crude anthropomorphic statue menhirs the Bronze Age has no sculpture to show in central Europe, but in Spain rock carvings of weapons are found on the Atlantic seaboard, and at Kivik and Bohuslan in Sweden rock carvings of

chariots, plows, and boats continued to the 10th century B.C. and to the beginning of a new artistic tradition in metalwork that spanned central Europe from the Alps to the Baltic. See HALLSTATT; VILLANOVANS; FRANCE: *Archaeology*; SPAIN: *History*; EUROPE: *Archaeology*. (WM. C.)

II. PREHISTORIC ASIA

This brief survey is limited to the art of prehistoric China and Japan; i.e., before the use of writing.

China.—As far as archaeological knowledge in the 1960s is concerned, the first truly historic period of early China, that is; the Shang (Yin) dynasty (c. 1523–1027 B.C. according to some authorities), seems to have emerged suddenly with a highly developed civilization. Writing, ceramics, bronze casting, sculpture, and, presumably, painting had attained a very high level under the Shang. This is clearly shown by the great number of materials recovered through numerous excavations since 1928 at the final site of the Shang capital, dating from about 1300–1027 B.C., and located in the northern tip of Honan Province near the present city of Anyang. These materials are not to be considered prehistoric art; however, available prehistoric artifacts include Neolithic pottery collected in abundance, especially in northern China.

After what has been called a Neolithic hiatus, a well-developed Neolithic culture appeared in north China near the end of this period about 4,000 years ago. Best known, perhaps, is the Yangshao culture, named after the type site discovered in Honan Province in 1921. This covers a large area in northwestern China and is characterized by the excellence of its ceramics, which had few equals (if any) for that time. The most spectacular Neolithic ceramics comprise the painted pottery found in many sites in a wide belt across north China. The Yangshao culture had its beginnings about 2500–2000 B.C., and this pottery is associated with burials. In shape and size the painted pottery objects range from a large- and medium-sized amphora type to smaller jars, bowls, and basins. The ware itself is technically excellent, fired at high temperature, and painted with considerable skill. The designs are (generally speaking) geometric, and are based on such elements as the circle, diamond, rhombic checkers, zigzags, triangle and rotary S curves, with a gourd motif, cross-hatching, and the so-called death pattern (a saw-toothed band) as common features. They are painted in black, brown, purple, and similar colours that contrast with the reddish colour of the ware. Of particular interest are those paintings which contain anthropomorphic or zoomorphic designs. In some cases, birds (for example, the whooper swan) are so ingeniously stylized that there is little question about their identity. A few quite naturalistic paintings of human faces and fish have occurred on the Neolithic pottery excavated at the important Pan P'o Ts'un site discovered since the Communist takeover in 1949. Most of this painting was done with a flexible brush, and it may be presumed that paintings, perhaps of a completely different nature, were also being done at this time on perishable materials. One of the most important problems remaining to be solved in this field is that of the origin of this painted pottery. Although there is still no general consensus, and some argue for an independent origin in northwest China, there is much evidence to point to a connection with ceramics from such areas to the west as Tripolye in south U.S.S.R., and even Iran.

A somewhat later wheel-thrown pottery of the Lungshan complex is also noted for its technical excellence. This type was first found at Lungshan in the eastern province of Shantung; later traces of it were found as far south as Hangchow and as far west as Szechwan. This ware is black or brownish, of remarkable egg-shell thinness, and so highly burnished that it still retains a mirror-like finish. It is on the whole undecorated, but a few pieces have been found that have simple, incised geometric designs.

While large numbers of carved personal ornaments made from shell, stone, clay, and bone have been discovered, only a very few objects have been found that can be regarded as sculpture in the strictest sense of the word. One of these is a small, highly stylized and unidentifiable animal figure found at the Sha Kuo T'un site in Liaoning, Manchuria. It is carved from marble and the principal features are suggested rather than clearly delineated; in spirit

it is close to some of the cubistic small animal sculpture of the Shang dynasty. Two others, small pottery figurines from Pu Chao Chai in Honan Province, are a crudely made bird and a simple but recognizable human. See also CHINA: *History*.

Modern examples of primitive art may be found in the early woodcarving of the aborigines in Formosa (q.v.), especially in that of the Paiwan group. Some of the motifs show a relationship to the art of Polynesia, and in one case a close parallel has been found to a motif used in the Dong-son complex of Indochina and southwest China about the third or fourth century B.C. (see INDO-NESEAN ARCHAEOLOGY AND ART).

Japan.—The wholesale Japanese adoption of Chinese Buddhism along with writing, art, and culture in general in the 6th century A.D. marked the end of Japan's scriptless protohistoric period. Before this time, Japan had passed through a still vague Paleolithic phase, a well-defined Neolithic stage, and a Bronze or Bronze-Iron period.

The prehistoric period in Japan is characterized by two principal cultures known as Jōmon and Yayoi (see also JAPANESE ARCHITECTURE). The first, literally "rope pattern," is named after a technique in pottery decoration, and the second after a street in Tokyo where this type of pottery was first found. Generally speaking, both types are distributed widely over Japan, but the earlier Jōmon is more common in the north and east while the later Yayoi is more common in the south and west. Jōmon pottery is rich in typology and shows considerable freedom of design. Decoration is accomplished by relief decor, spiral designs, and scraping. Of more artistic interest are peculiar and often grotesque clay figurines that may have been used for totemistic or fertility rites or may have served as penates at different stages in their development. These figurines show a progression from lower animal to human characteristics. In most cases they are skilfully executed, and incised, appliquéd, stamped, and shell- or cord-impressed.

Yayoi pottery seems to have its beginnings in the 3rd century B.C. and is mostly wheel-thrown. It is decorated with painted floral motifs, saw-toothed bands, and rectangular spirals in red and with combed patterns. Some pieces have crude, incised pictures that represent animals of various kinds and other scenes of a very elementary nature. Although there is evidence from certain aspects of decoration and shape to link some of the early Japanese pottery with the Gobi cultures and northeast Asia, it should be noted that there is no trace of influence from the Chinese painted pottery or the black eggshell ware.

Bronze was introduced from China by way of Korea about the first century A.D., but there was hardly a true Bronze Age because the Iron Age almost immediately followed. The most important indigenous Japanese bronze form is the *dōtaku*, a bell-shaped object, ranging from a few inches to almost four feet in height, which often contains cast or incised pictures in panels. The drawing, while very simple, is more advanced than that found on Yayoi pottery and represents animals, buildings, hunting, and domestic scenes. Clay sculpture during the protohistoric period is well known through the figures called *haniwa* which were buried around the perimeter of a tomb, apparently for protection. The earliest, dating from about the 3rd century A.D., were scarcely more than clay cylinders with embellishments of one kind or another. These later developed into human figures: armed guards, dancers, and musicians. Many of them are very finely executed in a realistic style showing much detail in clothing and armour. Many of the faces are painted with definite patterns in red. Other objects represented by *haniwa* are animals (especially horses), and many types of house.

Some actual paintings in the form of tomb murals survive from the protohistoric period. These consist mainly of abstract geometrical designs based on concentric circles, rectangles, diagonal lines, and arcs. Realistic paintings include such objects as horses, boats, quivers, and shields. These decorations are in black, red, blue, and white, and generally are of low quality. (R. C. RU.)

III. AFRICA

Traditional, predominantly tribal arts of subsaharan Africa were nearly unknown elsewhere until studied by 19th-century anthro-

pologists. Popular interest was aroused when early 20th-century European artists found African sculpture worthy of admiration. However, conservatism and commitment were often misread by outsiders as freedom, innovation, and self-expression.

Art may be understood best in the light of its cultural origins. Anthropological studies record the cultural role of the arts, but equally necessary are stylistic analyses, and historical and archaeological investigations.

History.—Much prehistoric art was probably of perishable material, and little is known of the early art of the great empires of Western Sudan or the more modest kingdoms of the forest areas. Yet archaeological discoveries of rock paintings in the Sahara, Nigeria, East and South Africa, as well as clay pieces of the Nok figurine culture of northern Nigeria, hint at a rich art predating Christ. Terra-cotta work of the Sao culture near Lake Chad and bronzes (technically, brasses) from Ife, Benin (*qq.v.*), and elsewhere in Nigeria indicate continuing activity from medieval times.

Rare instances of preserved perishable art (as in a collection in Ulm, Ger., dating to about A.D. 1650) closely resemble much more recent material. Similarly, style continuity (although modified) is apparent in Benin bronze casting over several centuries, in Dogon (*q.v.*) ancestor figures, in the relationship of little steatite Nomori figures of Sierra Leone to modern Mende (*q.v.*) wood carving, and in Kuba (*q.v.*) king figures perhaps extending over three centuries.

Despite its position outside the orbit of medieval Europe, Africa south of the Sahara long has been subject to outside influence. Phoenician traders probably made earliest foreign contact with northwest Africa; and Saharan trade routes have existed for 2,000 years. As early as the 7th century A.D. Islam entered the Sudan with displaced Arabs. After the 11th century the *jihads* (Muslim holy wars) spread the religion throughout Western Sudan. Arab historians and observers followed, some of them associated with the great medieval university and library at Tombouctou (Timbuktu). Likewise, coastal East Africa, as part of the ancient Indian Ocean trade system, has yielded large amounts of Chinese porcelain that have been of help in dating archaeological finds with which they occur. European contact with the west coast dates from the 15th century; significant penetration inland began about four centuries later.

African artistic traditions (including those allied to religion) survived traders, soldiers, scholars, missionaries, empire builders, and holy wars. The Islamic interdiction against imagery was widely resisted, as were early European entrenchments. By the 1960s, however, modern science and technology had undermined much of traditional tribal insularity and disrupted ancient ways. As a result, earlier art forms that reflected the older cultures were rapidly disappearing. Unlike much European and American work, traditional African art neither condemned nor questioned popular cultural values. Reflecting and contributing to the needs of people, art symbolized individual and tribal security, understood in such terms as wealth, prestige, health, children, wives, and crops.

However, there was room in this scheme for the individual skill of the artist. Skill was the basis for a respected and admired specialist group. The artist (usually trained through apprenticeship and working on commission) received rewards as a specialist

who contributed to the tribal sense of well-being.

Purely utilitarian objects that are unornamented or undecorated are omitted from this discussion. Relative aesthetic importance among the arts and crafts in Western cultures is not to be taken as indicative of relative prestige in Africa. Bambara (*q.v.*) blacksmiths, for example, have high status as artisans and (probably related to their specialism) as ritual cult leaders. Despite this, few of their products will be considered here. Specialist activities often are limited by sex: pottery is usually produced by women, wood carving by men; blacksmiths are men; women often decorated house exteriors. Widely differing tribal styles are readily distinguishable to experts, as in many instances are styles of individual artists.

Cloth and Clothing.—The simplest clothing consisted of penis sheaths or loincloths for men, bunches of leaves or small aprons for women. Wraparounds of bark cloth or woven cotton were common. Weaving by women was done on broad vertical looms, that by men on narrow horizontal looms. Cotton, raffia, and occasionally wool or imported silk were utilized. Woven patterns were usually stripes, checks, or simple diagonals or zigzags. The Kuba and other Congo tribes are noted for raffia cut-pile "velvets" which carry geometric patterns that have influenced wood carving on boxes, cups, and drums.

Bark cloth and woven materials were coloured with native paints or dyes. Particularly fine printed decorations among the Ashanti (*q.v.*) were applied with small stamps made of calabash. Yoruba (*q.v.*) women produced richly patterned indigo-and-white cloths (*adire*) by tie-and-dye and by a resist method similar to batik but using a starch paste instead of wax; stencils of zinc, tin, or leather were used as well. Some Western Sudanic tribes, particularly the Bambara, produced rich light-on-dark motifs by a discharge method in which dyed cloth was bleached in patterns by special mud and soap.

A number of West African and Congo tribes produced cloth appliqué which in most instances was restricted to royal or ritual use. That produced for royalty by a family guild among the Dahomey (*q.v.*) is among the most impressive.

Embroidery was most probably imported from North Africa along with such typically embroidered clothing types as loose trousers and robes, turbans, and skull caps. Similarly, so-called Moroccan leatherworking may have been imported into the Western Sudan; dyed leather sandals, containers, scabbards, and horse trappings were decorated with patchwork and appliqué designs like those used in embroidery.

Personal Ornamentation.—Palm oil, vegetable butter, and powdered red camwood (*tukula*) were widely used as cosmetics, along with such Islamic imports as kohl and henna (see COSMETICS AND COSMETOLOGY). Facial and body scarification, and elaborate coiffures were common, and were accurately depicted in figure carvings. Jewelry was of ostrich eggshell, iron, brass, silver, gold, ivory, glass, and even twisted elephant hairs. Locally manufactured glass was worked into beads and bracelets at Ife and Bida (*q.v.*) in Nigeria. Heavy neck rings, anklets, and bracelets were made of forged iron or cast brass. Amulets were worn less as ornament than as protection or as guarantees of well-being.

Utensils.—Because the potter's wheel was unknown south of the Sahara, pottery was hand-molded. Fired in open pits at a fairly low temperature, it tended to be fragile and crumbly. Domestic ware often had impressed or incised patterns, was burnished or coloured with vegetable juices or resins after firing. Ritual or prestige ware could be molded or even sculptured; often a mixture of techniques was used on the same vessel.

Utilitarian wood or calabash objects were frequently incised or burned in linear patterns. Wooden stools, headrests, and chairs (the latter influenced by European prototypes) were similarly ornamented, and were occasionally decorated with carved figures as among the Luba, Chokwe (*qq.v.*), Basonge, and the Cameroons Grasslands tribes (where some chief's stools were completely covered with decorative beadwork). The Baule (*q.v.*) are noteworthy for their heddle pulleys (for horizontal looms) topped with animal (including human) head forms; the neighbouring Guro and Senufo (see KWENI; SENUFO), and the Yoruba and Dogon also

decorated pulleys. Ashanti cast-brass weights (for weighing gold dust) depict humans, other animals, vegetables, and geometric forms. The Nupe (*q.v.*) were excellent metalworkers, manufacturing a variety of vessels decorated with repoussé (hammered or pressed) designs.

Throwing-knives of the Congo, often with punchwork designs, exemplify finely forged, abstract forms of iron weapons. Blacksmiths produced such ritual utensils as single or double gongs, Bambara staffs topped with equestrian figures, and Yoruba and Benin shrine pieces containing mammal and bird forms.

Architecture.—House types ranged from shelters of boughs and leaves, as among nomadic Fulani herdsmen and Congo pygmies, to elaborate mud structures based on North African prototypes. A typical hut consisted of a windowless mud cylinder pierced by a single door, and topped with a conical, thatched roof. One house type (Yoruba) comprised a series of rectangular rooms around an open court or rain-storage area. Families were often found to live in compounds composed of a number of huts surrounded by a mud wall, or mat fence of woven fibre. Carved wooden houseposts, doors, lintels, sills, and jambs were used widely in West Africa. Particularly outstanding architectural sculpture was produced in the Cameroons Grasslands, Nigeria, Ivory Coast, and Western Sudan (*see DWELLINGS, PRIMITIVE*).

Painting.—African painting (and engraving) includes permanent works on rock surfaces, and those that cannot outlast the mud walls which carry them. The latter, essentially architectural decoration, may be figurative (*e.g.*, on Ibo [*q.v.*] houses in Nigeria) or geometric and essentially nonpictorial (*e.g.*, patterns on Mangbetu and Transvaal Ndebele [*qq.v.*] houses). In this category also belong sgraffito designs, and molded and painted mud decorations in low relief.

Main areas of North African prehistoric rock paintings and engravings have been discovered in the Sahara Atlas Mountains, the Ahaggar Mountains and Tassili, and in the hills of the Libyan Desert. Earliest works seem Neolithic and may not predate 4000 B.C. In later examples Egyptian influences are to be noted and some seem to extend into Roman times. Except for extinct buffalo, modern animals (no longer found in the area) are depicted, including lion, elephant, panther, antelope, gazelle, ox (apparently domesticated), ostrich, and (more rarely) giraffe and rhinoceros. The more naturalistic representations seem to be the earliest.

Some human representations resemble the lively silhouette style of Paleolithic eastern Spain but are probably more recent. Others are grotesque roundheaded figures (playfully called Martians by one author) or hourglass figures. North African rock art may link Paleolithic arts of western Europe with Bushman (*q.v.*) art of South Africa, although this was far from settled in the 1960s. Distribution of Bushman art suggests a migration southward; it is found from Tanganyika through the Rhodesias into South Africa, fanning out south of the Kalahari Desert.

Earliest Bushman works seem to be engraved animals; these and large painted elands precede human representations. Later, hunting, fishing, warfare, and more stylized dancing scenes showing people and other animals were produced by ancestors of contemporary Bushmen. Old paintings were retouched and new ones created until about a century ago; some of the most recent show Europeans in covered wagons, and on horseback.

The tradition of rock painting still existed in the 1960s among the Dogon of Western Sudan; connected with ancestor beliefs, it depicts masked figures that appear in funerary dances. Excessive and dangerous spiritual powers of the masks were thought to be transferred to the paintings, making the masks safe for use.

Sculpture.—Major sculptural traditions existed in tribes of the tropical rain forest (and adjacent savanna) that extends uninterruptedly along the Guinea coast into the Congo River basin.

Most sculpture was of wood (much of it painted) although other materials were utilized. The earliest-known sculptures (about 2,000 years old) are of terra cotta, and come from the Nok culture of Northern Nigeria; they represent humans and other animals in a decidedly Negro African style. Other terra-cotta sculptures are from the Sao culture near Lake Chad (dated about A.D. 1200), and Ife in southern Nigeria (about the 15th century). More re-

cent terra-cotta traditions have been reported from the Ivory Coast, Northern Nigeria, Ghana, and elsewhere.

Stone sculpture is quite rare although steatite figures of no great age have been discovered in Sierra Leone, at Esie in Western Nigeria, and in the southern Congo. Older examples have been found at Ife and Zimbabwe, but none seem truly ancient (*see ZIMBABWE*).

Brass, cast by the lost-wax process (*see SCULPTURE TECHNIQUES: Bronze Casting*), was usually the prerogative of royalty, as in Dahomey, and at Ife and Benin in Nigeria. Ife castings appear quite naturalistic and are among the finest sub-Saharan art. First reported by Leo Frobenius (*q.v.*) early in the 20th century, they are mostly hollow-cast heads, possibly used in ancestral rites. Benin "bronzes" were reported as early as the 16th century, but not until the 1890s did they become well known in Europe. Local traditions indicate the technique and the first caster came from Ife, perhaps in the late 13th century. Heads representing deceased Benin kings, often supporting a carved ivory tusk, and plaques used as architectural decoration predominated. Excellent thinly cast pieces, fairly close to the style of Ife, gave way to heavy, crude, overdecorated pieces of the later 19th century.

Precious metals, particularly silver and gold, were usually the prerogative of royalty, as among the Baule and Ashanti. Ivory carving was widespread, with fine pieces coming from Benin and the neighbouring city of Owo, and from a number of tribes in the Congo. Wood was usually carved green; tradition prescribed the choice of wood, the rituals and taboos governing the artist and his tools, and the sacrifices that consecrated the completed object.

Boldly carved masks of human and other animal forms (often combined) were usually worn with elaborate, totally concealing dance costumes. Representing spirit forces, and often manufactured in secret, the masks were used in rituals relating to puberty (Pende and Yaka initiation masks), agriculture (Bambara *Chiwara* masks), policing and judicial functions (Kuba *Shene Malulu*, and Bambara *Kono* masks), and ancestor worship (Yoruba *Egungun* masks). Such functions were combined in Poro Society masks of Liberia and western Ivory Coast (*see MASK*).

In figure sculpture, heads tended to be large, legs squat, and torsos and faces generalized (there seems to have been little or no physiognomic portraiture). Although static, and usually frontal and symmetrical, stance was descriptive of normal carriage and gesture. The carvings served for ancestor worship (Dogon and Bambara), dispelling evil (Fang and Kota), fertility (Ashanti *Akuaba* figures), healing (Lower Congo), personal well-being (Ibo *Ihenga* sculpture), secret societies (Lega *Mwami* society), and as commemorative statuary (Baule portraits and Kuba king figures). *See also AFRICA.* (Rv. S.)

IV. OCEANIA

In Oceania four major art styles correspond to the cultures of Australia, Melanesia, Micronesia, and Polynesia. A certain uniformity in style may be observed in Australia and Micronesia; Polynesia and especially Melanesia show regional variations.

Typical of other primitive cultures, this art had religious or social use and was rarely made for its own sake. Magico-religious aspects were especially strong in Australia and Melanesia. In Polynesia and Micronesia, art was also credited with magical power, but it was given most emphasis for social display.

These were originally Stone-Age cultures, and metal tools and weapons appeared after European contact in the 19th century. Consequently even the art of the recent past derived from a Stone-Age technology. With such limitations in tools and techniques, artistic achievements in Oceania seem all the more exceptional.

Knowledge of prehistoric Oceania is limited, but toward the end of the Ice Age there seem to have been three or more migrations out of southeast Asia (*see OCEANIA*). The earliest moved into Melanesia and Australia; later migrations penetrated Melanesia and later Micronesia and Polynesia. Knowledge is so limited that little more can be done than to speculate on the broad pattern of migration. Examples of art from this period are isolated and difficult to relate to other cultural developments. There are remains of stone platforms in Micronesia, the Society Islands, and

the Marquesas; handsome sculptured mortars and pestles have been unearthed in New Guinea; petroglyphs, some of which may be ancient, occur throughout Oceania; and design motifs from as far east as the Marquesas resemble some from ancient China. Such motifs may be survivals from a very early period. It may be assumed that there was a great quantity of prehistoric art, little of which has survived. This discussion is concentrated on material produced during the last 150 years and now deposited in the large collections of Europe, America, and Australia.

Australia.—Simple living conditions and few possessions typify the nomadic tribes of Australia, but they show complex social organization and elaborately developed supernatural beliefs (see AUSTRALIAN ABORIGINES). Some of their sacred art is ascribed to all-powerful beings of an ancient, mythical "dreamtime." Although some rock paintings and engravings are secular, those of greatest importance (and probably of greatest age) are held sacred. Several styles in painting range from tiny linear, animated figures to large pictures of the supernatural Wandjina beings (northwest Australia). Found on rock surfaces of shallow caves and shelters, they are sometimes compared in location and technique with rock art in Africa and Spain. However, the so-called X-ray style, in which internal organs are shown in stylized detail, is uniquely Australian. This device is also used in paintings on bark from Arnhem Land (northern Australia) that represent figures, animals, and plant forms in flat areas of massed lines and dots, sometimes spread over the entire surface.

Painting techniques and media of Australia are similar to those throughout Oceania, although allowance should be made for local variations and the recent use of trade colours. The pigments were coloured earths, red and yellow ochres; white came from natural lime deposits and from burned shell; black was charcoal or manganese compounds. Mixed with water, the pigment was applied with the tip of a chewed stem, a feather, or even the finger. It was sometimes mixed with tree sap or oil or treated afterward with fixative made from honey or wax.

Sculptured figures in wood, clay, and wax are rare, but clusters of abstract carved and painted commemorative poles are erected at burial grounds on Melville Island off northern Australia. Carvings on tree trunks and on ground surface at some ceremonial grounds are similar to the highly symbolic totemic designs on spear throwers, shields, and sacred bullroarers and churingas; the designs applied to these are engraved in concentric circles, spirals, loops, and zigzags (see BULLROARER).

Melanesia.—In Melanesian art the principal theme is a figure that represented remote mythological beings or images of important ancestor cults. Carving and painting the figures or constructing elaborate ceremonial masks and costumes were important since they were held to maintain contact with the supernatural. Much of the vital and intense Melanesian art seems spectral and fantastic.

New Guinea.—The largest island of Melanesia, New Guinea has been divided into nine roughly distinct style areas: (1) In the northwest coast and Geelvink Bay area art is curvilinear (as throughout New Guinea generally) and uses much open scrollwork, probably influenced from Indonesia. (2) Another curvilinear style combined with rounded sculptural forms occurs in the Humboldt Bay-Lake Sentani district east along the north coast. (3) The most important art style for richness and variety is from the area of the Sepik and Ramu rivers, and adjoining coastal regions. Variations are so highly developed as to represent a cluster of substyles with robust, exuberant application of flowing carved and painted patterns. Some sculpture, figures, and masks show what is termed the "beak style." (4) In the Astrolabe Bay and Huon Gulf area an angular, pointed motif is frequently used in decorating the stiff, static forms of the masks and figures. (5) On the eastern tip of the island and in the Trobriand, D'Entrecasteaux, Woodlark, and Louisiade archipelagos, technique is highly developed but art is conventional. A typical scroll design recalls that of the northwest coast Geelvink Bay region. (6) A colourful, vigorous style is found in the Papuan Gulf area. (7) Small islands between New Guinea and Australia show a distinctive Torres Strait style. (8) Distinguished for fantastic ceremonial art are the Marind-Anim

people along the east coast of Frederik Hendrik Island and the adjacent mainland. (9) The Asmat and Mimika tribes of the southwest coast carve and decorate in an intricate, highly individual openwork, often spectacular. Knowledge of the interior is incomplete and few examples of art are known from that region.

In many areas of New Guinea, art centred on the men's house (*eravo*). In the Papuan Gulf area the 10- to 15-year ceremonial cycles began with the erection of a large *eravo*. Inside the *eravo* ceremonies were planned in secret, costumes were made and stored, and masked dancers emerged from the house to perform.

As a rule the thatch roof was given prominence in houses; it was pyramidal with a tall spire, or saddleback, or sloped steeply down toward the rear from the high front (which in some examples rose more than 50 ft.). The drop of the roof along each side in many examples (or styles) eliminated side walls, but the front was often covered with painted panels or carving, or decorated with a large house mask. Inside were displayed drums, bullroarers, and carved and painted plaques associated with the ancestor cult.

For ceremonies every effort was made to disguise human aspects of dancers' bodies and to create a supernatural presence. Over a superstructure (in some cases 20 ft. high) a costume was made from a variety of such materials as feathers, fur, shell, teeth, and leaves. The central part of such a construction was a mask (*q.v.*), the image of a mythological or ancestral being. With the exception of the northwest coast Geelvink Bay area, Humboldt Bay-Lake Sentani area, and among the Massim people, masks which varied greatly in form and materials were used in all regions. From the Asmat area came netted fibre masks; some from the Sepik and the Papuan Gulf areas were of wickerwork. Bark cloth stretched over a light framework was made into large masks in the Papuan Gulf area, and turtle-shell plates were fastened together to make them in the Torres Strait islands. The most common forms were carved from wood in the Sepik and Huon Gulf areas, usually polychromed, often decorated with fibre, pig tusks, or encrusted with cowrie shells.

Wood was also carved into such objects as neck rests, hooks, stools, drums, bowls, canoe-prow ornaments, shields, memorial tablets, house posts, commemorative poles, and single figures. Commemorative poles from the Asmat are tall and spectacular, jutting from the top is a pointed wing consisting of a carved openwork panel with figures entwined in vinelike tracery. These carvings like many others in New Guinea are light and open, and whether stiff or sinewy the figures are composed of thin stemlike forms rather than heavy sculptural masses.

In figures from whatever area the head is large and emphatic; in the "beak style" centred in the Sepik area the nose is given great prominence, and may project far below the chin. The importance of the head is also apparent in specially treated and preserved skulls of ancestors and enemies. To control the spirit of the original owner the skull was painted and modeled over with paste; hair, feathers, shell, tusks, or carved eye and nose projections were attached. For preservation and display the decorated skulls were hung from elaborately carved and painted hooks suspended from rafters in the men's house.

Although the human image is the most important subject, fish, snakes, crocodiles, and especially birds are all significant in New Guinea mythology and art.

Most sculpture is polychromed but painting on plane surfaces is rare. In the Humboldt Bay-Lake Sentani area sheets of white bark cloth are painted with dark spidery lines, creating clan emblems of fish or serpents. In the Sepik, flattened Sago palm leaf sheaths cover the front of the men's house. These are painted with human faces and animals in a flowing, curving line that spreads over the entire surface. These painted panels are typical of the curvilinear quality of the art of New Guinea. Combined with the flowing line are concentric circles ringing large dots, and a toothed line and chevron motif used for contrast and variation.

Bismarck Archipelago.—North of New Guinea lie New Britain, New Ireland, and the Admiralty Islands, comprising the Bismarck Archipelago. In the Admiralties masks were not made but figures of crocodiles, fish, and birds (some in large size) were carved and painted in a stiff, rigid style. Probably ancestor images, the figures

were often stereotyped but some of the finest are handsome in stately dignity.

New Ireland art is rich, intricate, and involved. Sculpture showed great virtuosity in carving and in a profusion of applied painted patterns. Birds, fish, snakes, pigs, and such mythological symbols as the sun and moon were interwoven in almost medieval fantasy. In the pole carvings, for example, these and such elements as one animal biting another encircle the human figure to create open cage-like sculpture. The poles, figures, panels, and masks were exhibited in secluded courts as part of the so-called *Malanggan* cycle of ceremonies in commemoration of dead ancestors. Masks were carved and painted in the same complex style, with combs, crests, and large earlike appendages attached to the main carving. The very sacred *uli* figures from central New Ireland with both male and female qualities are in sharp contrast to the extravagant *Malanggan* art. They are monumental, heavy, and aggressive.

There are several distinct styles in New Britain, the largest island of the archipelago. Masks are outstanding; realism is pronounced in two quite different types: one of large massive forms in wood, the other in which the face was made by modeling over the front of a human skull. In strong contrast to these are masks of the Baining and Sulka tribes both living on the Gazelle Peninsula. Those of the Baining that were used in night snake dances are of painted bark cloth stretched over a framework; some are gigantic with long tubular snout and bamboo tail. At the centre, rising from the head of the dancer and expanding like a bellows, are the forehead, nose, lip, and tongue.

Sulka masks were of a conical framework over which long strips of pith were sewed that covered the dancer's upper body. Towering over this was a superstructure (up to nine feet in diameter): an umbrellalike disk, or a carving of a figure or bird. The spectacular effect was enhanced by painting the base bright pink, so unusual a colour in oceanic art.

The Solomons; New Hebrides; New Caledonia.—In the Solomon Islands, the combination of earth reds and yellows with black and white that prevails throughout most of Melanesia is much less frequent than is a polished black surface inlaid with bands of mother-of-pearl pieces. This style is found repeatedly, applied to strong, often elegant shields, clubs, paddles, bowls, canoes, and figures. A limited number of life-size standing figures were made for funerary purposes. More numerous are small, seated, large-headed figures used in initiation rites, to decorate canoe houses, or as guardians lashed to fronts of great canoes. The head is a counterplay of clear-cut planes, convex across the forehead and around the chin, concave in the cheeks and nose. The same approach (though less stylized) may be seen in the modeling of trophy and ancestor skulls, their black-gum surfaces inlaid with mother-of-pearl.

Breast ornaments were made of white disks ground from the giant *Tridacna* clamshell, overlaid with dark turtle shell cut in angular openwork patterns. These and similar pendants from the Admiralties and New Ireland are highly valued by the people of the area.

In the New Hebrides, art is important in ceremonies marking progression in rank among members of men's societies. For each step, large (5- to 12-ft.) images were carved from tree-fern trunks and set up in clusters near the men's house. Deeply undercut grooves defined droll faces with large disk eyes and flaring nostrils. The rough texture of the fern was finished with clay and brightly painted. The same rites employed masks representing mythological beings. A common form, a conical helmet, was modeled with paste over a fibre base with two, four, or even more faces painted in bright reds and blues—probably trade colours. Curved pig tusks that were thought to add to the mask's power and increased its value were inserted around the mouth.

That art remaining from the extinct culture of New Caledonia is limited in variety of form, although it has a distinct style (perhaps lacking in finesse, but vigorous and forceful). Carved wooden masks, some representing a sea spirit, were attached to a fibre base covered with hair and feathers to fit over the upper body. Some had great hook noses and were black-brown, to create a sombre

and grotesque effect. Ancestor images were carved in the round and also in relief. These and family crests were carved on tall, flat spires and doorposts of the large circular houses. The face (often the only recognizable part) was broad and flat with eyes, nose, and mouth completely filling the available shape.

Micronesia.—Material culture in the Mariana, Caroline, Marshall, and Gilbert island groups imposed severe restrictions and Micronesian art is the simplest of Oceania. Sculpture is rare, and masks are all but unknown; decoration is minimal, and basic form stands out clearly and effectively. To realize such sensitive design Micronesian artists developed exceptionally fine craftsmanship, evident in secular, functional work. Such items as coconut-grater stools, wooden bowls, and even outrigger canoes were planned to achieve subtle balance and contour, and to utilize materials fully.

Houses are skilfully made; the fronts of those for young men in Palau (Carolines) show carved or incised, painted representations of mythological or historical events. On Mortlock Island in the Carolines ceremonial house fronts were mounted with large flat masks as protection against typhoons. The few sculptured unornamented cult images were moderate in size, unpainted, and appeared sedate and impersonal.

Polynesia.—Local variations in the culture of Polynesia are not so great as in Melanesia, nor is the art of separate island groups so distinct. In the west, Fiji Islands culture is primarily Melanesian but art is Polynesian. Central Polynesia includes Tonga, Samoa, the Cook, Austral, and Society islands. Along the eastern edge are the Hawaiian Islands, the Marquesas, and Easter Island; far to the south outside the Tropical Zone is New Zealand.

Much Polynesian art is formal, stylized, and created by specialists. As in Micronesia, secular objects were well designed; e.g., wooden oil dishes from Fiji or polished wooden bowls with suave, flowing contour from Hawaii. Wooden bowls in the Marquesas and feather boxes in New Zealand were covered over-all with relief patterns. Such weapons as clubs also were carved in unit motif and inlaid with shell; in some areas they were three-dimensional and sculptural.

In the hands of priestly groups, religion was more formalized than in Melanesia. In some areas ceremonial paddles, adzes, or even fly whisk handles replaced cult images. The finest examples of these carvings show strong, simple contours that served as foils to carved, angular decoration over the full surface.

Most wooden images were unemotional, stylized representations of gods or deified ancestors (as in figures from the Marquesas). Slight swellings indicated parts of the basically columnar body, with low relief for details of hands and face. Figures from Fiji and Central Polynesia differ in detail, but also were stiff and conventionalized.

Not all such representations were so detached in feeling; more intense, stylized expressions are seen in large, menacing Hawaiian war-god figures with oversize crested heads; or in contorted expressions on carvings by the New Zealand Maori. Unusual emaciated images of male ancestors come from Easter Island; stiffness is relieved throughout by curves along rib cage, backbone, hips, chin, and brow.

Stone is used much less often than wood, but some of the largest and most impressive Oceanic sculptures are monumental stone figures from Easter Island (*q.v.*). Carved from volcanic tufa, averaging 12-15 ft. tall, they weigh three to four tons. Set up on mortuary platforms or on hillsides, the figures have sloping facial planes with cheeks, nose, and brow projecting over deep-set eyes.

Pole and thatch houses and temples in Polynesia were well made, but simple and moderate in size; only in New Zealand can they be compared with the large men's houses of New Guinea. The Maori built a great council house in each village, requiring the efforts of a whole community in support of specialized craftsmen. The house was gabled, rectangular in ground plan with a projecting porch at one end; gable, door, and often the entire house front were covered with low relief carvings. Inside, the walls, rafters, and posts were either carved or painted. Small, stilted storehouses were similar in form and even more lavishly decorated with exterior carving around all four sides.

(particularly tribal chiefs) were believed to derive their power. This Caribbean art died out under harsh European rule after the 15th century.

South America.—North.—In northern South America, tropical forests prevented growth of large populations, great temples and palaces, powerful kings, or elaborate ceremonialism. Nevertheless, Indians of Brazil, parts of Ecuador, Colombia, and Venezuela developed unusual art forms that continue to thrive in the more remote Amazon jungles.

The earliest shell and bone ornaments, and stone carvings of mammals and fish are found along the Atlantic coast. In the interior, particularly along the Amazon River, burial mounds of earth yield giant urns, smaller effigies, and vessels of many unusual shapes. These were modeled with figures and covered with intricate scrollwork painted or cut from the clay surface as in wood carving.

In more recent times wood, bark cloth, feathers, skins, seeds, and iridescent beetle wings were made into tall dance headdresses, grotesque spirit masks, shaman's implements, and personal decorations. Trophy heads, human and other animal skulls, covered with vivid feathers, paint, and fibre, were macabre, colourful ornaments. Undoubtedly, few pre-Columbian objects of such perishable materials survived the humid climate.

The heterogeneous art of Colombia and Ecuador derives from such far-distant styles as that of the Central Andes (a pre-Columbian focal point for aesthetic ideas). There were scores of ceramic styles, clay effigies, and masks that vary from hook-nosed, puffy-eyed, amorphous-bodied types in Colombia to stylized, carefully detailed figurines of coastal Ecuador. These peoples (especially some Colombian tribes) produced outstanding goldwork; such intricate techniques as lost-wax casting, gilding (*q.v.*), and filigree were used in ornaments and ceremonial paraphernalia for the aristocracy. In the Colombian highland district of St. Augustine, numbers of massive fanged heads, and human and other animal idols were erected around temples and mounds at very early ceremonial centres. Idols, reliefs, and curved thrones supported by crouching figures exemplify Ecuadorian stone sculpture. Although Spanish chronicles describe large figures of wood, royal featherwork costumes, and painted textiles, these forms have long since perished as has native culture.

The Andes.—Civilization in the Central Andes equalled that of Middle America; reaching a peak in Peru and highland Bolivia, its impact was felt in distant lands. Central Andean art had its inception early in the 1st millennium B.C. with the powerful and inventive Chavín styles (see **ANDEAN CIVILIZATION**). Principal motifs, based on a Chavín cult of a fanged feline deity, were on pottery, in sculpture, and in ornament. For about the next ten centuries three artistic traditions characterize an age comparable to the Classic period of Mesoamerica.

Art styles of the Peruvian north coast tended to be realistic, three-dimensional, and strong in expression rather than in colour. This culminated in the magnificent art of the Mochica; ceremonial ceramics, modeled or finely painted in browns and beiges, depicted everyday life. Gold ornaments inlaid with turquoise, cast copper and silver, and delicate wood carvings attest to Mochica skill. Art was for tombs of the aristocracy or for pageantry around massive pyramids and temples, many of which bore brightly painted murals of priests and gods.

On the south coast a colourful, decorative, two-dimensional art of supernatural beings and symbol was emphasized. Among the Paracas and Nazca peoples a dominant activity was the creation of richly painted ceramics and sumptuous textiles as funerary goods. Designs vary from stylized life forms to depictions of complex deities in a maze of heads and appendages; hammered gold, carved wood, and featherwork also are found among tomb offerings.

A third tradition that centred in the highlands excelled in architecture and stone sculpture; the enigmatic Chavín art bore its greatest fruit in the northern highlands. Centuries later the temples, courts, and gateways of Tiahuanaco, a vast Bolivian ceremonial centre, were the setting for enormous sculptures and reliefs of characteristic angular running figures, puma, and condor-head motifs. Tiahuanaco expanded into an empire and these motifs

spread throughout the Central Andes. They mixed with and engulfed waning Classic styles of the coast to yield the most brilliant of Tiahuanaco textiles and ceramics.

This brief Tiahuanaco imperialism heralded the secular Post-classic period; technically excellent art tended to be decorative and overrefined. The Chimú revived elements of Mochica style in black molded ceramics and elaborate goldwork, but most of their objects are stiff and mass-produced. On the central coast rough black-and-white ceramics and figures were relatively stereotyped, as were textiles, featherwork, and woodcarving. Typical small south-coastal geometric designs are pleasantly decorative but lack the earlier vitality.

The Inca empire represents the last great aboriginal Andean episode; its art emphasized technical mastery and expert craftsmanship. Architecture, ceramics, and textiles derived beauty largely from functional design and skilful construction. Indians in the highlands of Peru and Bolivia still (1960s) wove geometrically patterned textiles not unlike those of the Inca; other crafts such as pottery making survive, but designs are primarily European.

Although the force of Central Andean art penetrated far south, beyond the forbidding Atacama Desert, the simple native cultures of what became Chile and Argentina evolved slowly. Little interest was given to ceremonial and artistic elaboration; instead, these peoples of the Southern Andes buried their dead with handsome useful objects: wooden tubes and palettes (for snuff, and carved with fauna), clay effigy pipes, bone spatulas and flutes, decorated gourds, baskets, textiles, and pottery. Many designs derived from the Tiahuanaco and Inca, but distinctive local forms include burial urns painted and modeled with large stylized human figures. Cast bronze and copper plaques in relief show curious surrealistic faces, figures, or serpents.

After the Conquest the Indian population in Chile and Argentina was drastically reduced. Among the groups remaining in the 1960s, silverwork, basketry, and textiles were still made in limited quantities; in rare instances, shamans still exorcised with magic carved poles and tambourines.

PRIMITIVISM, an outlook on human affairs which sees history as a decline from an erstwhile condition of excellence (chronological primitivism); or, the view that salvation lies in a return to the simple life (cultural primitivism). The term was introduced by A. O. Lovejoy.

Linked with this is the notion of nature and what is natural, as a standard of human values. Nature may mean what is intrinsic, objective, normal, healthy, universally valid. Various senses depend on whether the natural is set over against historical development; against artifact and contrivance; against law, custom, and convention; or against rational mental activity. The first two contrasts belong to chronological, the last two to cultural, primitivism. Sometimes several senses are held at once.

The first great doctrine of primitivism in European literature figures in Hesiod's *Works and Days*, with its myth of the Five Ages. First came "the Golden Age," in which a happy primitive people lived in luxury (their life was far from ascetic) and in perpetual peace; there is a steady decline (except for the intervening Age of Heroes) until the present or Fifth Age, sinking into moral and physical decay. The old legend continued to be popular after Hesiod's time; Empedocles, Aratus, Tibullus, reecho it. This Greco-Roman conception of a Golden Age, later almost a platitude and a topic for satire, was basically a chronological primitivism. Ovid's account in the *Metamorphoses* supplies details missing in the earlier tale; he emphasizes the first age as a reign of justice, when men were good by nature, and therefore had no need of lawyers, judges, or courts. Another version identifies the Golden Age with the reign of Saturn; the most famous text is Virgil's Fourth Eclogue (the Messianic Eclogue), which also describes a future Golden Age. Nonmythological treatments of the idea of human and cosmic decline occur in Lucretius' *De rerum natura*, Dio Chrysostom, Pliny, and Aulus Gellius.

Cultural primitivism comes to the fore in Cynicism, whose doctrine was lived by Antisthenes (a pupil of Socrates and the Sophists) and Diogenes. The philosophical ideal of self-sufficiency, as recast by the Cynics through the notion of nature as a norm, entailed a rejection of luxury, property, rules of social decorum and tact, and all moral rules (including sexual prohibitions). Roman Stoicism derived much from the Cynic teachers and, as through Seneca, greatly influenced primitivism in the 16th and 17th centuries.

Primitivism first enters Jewish and Christian thought through interpretations of the story of the Garden of Eden. The allegorical reading of Genesis by Philo Judaeus (1st century B.C.) shows primitivist notions of Cynic and Stoic origin, and repeats the theory of human decline. At the end of the 2nd century, Theophilus, bishop of Antioch, gave an antiprimitivist interpretation of man's condition in Paradise, as the first stage in a continual advance. Succeeding patristic writers, however, tended to adopt a primitivist view. St. Basil says that the Fall initiated the decline of both man and nature; St. Ambrose went so far as to call the best state that of Adam before the creation of Eve (apparently overlooking Gen. 2:18), and intimates that the first man, if left to himself, would not have fallen. St. Ambrose above all patristic writers echoes the classical tradition of primitivist communism. He describes the child, who is innocent, as following the *lex naturae*; he is like Adam before the Fall. The Marcionites, who made nature a norm of evil, provoked Tertullian to a strong defense of the sensible world ("God has made nothing unworthy of himself"). Lactantius even has a strain of hedonism, against the extreme Marcionite asceticism and contempt for the body and the sensible world derived ultimately from St. Paul. St. Augustine had to adopt the same praise of nature (in the sense of "the whole of things") in arguing against the Manichaean dualism.

The Christian emphasis on poverty, discipline, modesty of dress, moderation of desires, was influenced by the Cynic and Stoic

primitivist ideals of a natural life. Some early heretical sects, however, made a different use of nature as a norm. The Carpocratians preached an extreme form of community and equality, both economic and sexual, according to their idea of the state of nature. But the early Christian advocates of asceticism, in rejecting sexuality and even suspecting perfect health, go farther than the Cynics.

Primitivism in the Middle Ages continued to advocate poverty, communism, abstinence, and the simple life, by appeal to the "state of nature" and to the condition of Adam in Eden, as well as to the model of the primitive church of the early Christians. This new retrospective ideal figured decisively in the polemics of the Reformation. Contempt for man, and assertions as to his degeneration, are widespread; the tradition culminates in Pope Innocent III's *De contemptu mundi* with its famous passage on the superiority of even plants to man. However, considering that the fall of man was blamed on his quest for knowledge, and that early Christians had rejected classical rationalist culture and morals, the antiintellectualist tradition of Catholic Europe remained surprisingly weak. Among its few supporters were Pope John XIII and Bernard of Clairvaux.

The idealization of savages is an example of pure cultural primitivism. The Scythians were praised by Euphorion, Strabo, Cicero, Horace, Virgil, and Ovid among others for their vegetarianism, their communism, their justice, and their simple lives. Imaginary primitive groups similarly eulogized include the Cyclops (Homer, Plutarch), the Hyperboreans (Pindar, Herodotus, Diodorus Siculus, Aelian, Pliny, Pausanias), and the Arcadians (Xenophon, Plutarch). The earliest Christian writers abhorred the savage, whose life was not in accordance with Scripture. An exception to this was Salvian, a contemporary of St. Jerome, who declared savages superior to civilized Christians. There is, however, a Christian tradition of an earthly paradise, parallel to the pagan legend of the Island of the Blessed. This tradition begins with Origen, figures in the writings of St. Brendan (a 6th-century Irish monk) and St. Anselm, and reaches a famous expression in the 12th-century legend of the country of Prester John. That the accounts of the 14th-century explorers are written in primitivist language is partly due to this unbroken tradition.

Medieval Christianity also exhibits some views which are chronologically antiprimitivist but culturally primitivist. Foremost among these is the doctrine of the Three Ages, in Joachim of Fiore (c. 1135–1202). According to this, history is a progress from immaturity to maturity, from the Age of the Father to the Age of the Son to the Age of the Holy Spirit. We find the antiintellectualism of cultural primitivism: in the Age of the Holy Spirit rulers will be children; the spiritual man of the Third Age will be full of grace, not knowledge. Similarly, many Christian groups, particularly heretical ones, hold out a perfect future for man, often conceiving it as culturally primitivist. The paintings of Hieronymus Bosch have led critics to regard him as a member of the Adamite sect, who identified Christ with Adam and pursued salvation through ritual nakedness and sexual liberty.

Primitivism played a minor role in Renaissance writing: two notable exceptions are Erasmus' *In Praise of Folly*, which ends with the exaltation of the Christian fool whose folly is wiser than reason, and Montaigne's "Of the Cannibals" (Book I, ch. 30 of the *Essays*). A new crop of primitivist ideas came with the Reformation. Both Lutheranism and Calvinism stress the return to an uncorrupted, and therefore primitive, form of Christianity. The numerous sects which arose at the time (persecuted by Catholic and Protestant authorities alike) generally carried their imitation of early Christianity even further, both in emphasizing the Bible and the experience of conversion, and in distrusting bureaucratic church government and discipline. The most extreme group was the revolutionary community of Anabaptists at Münster (which was destroyed in 1535); there, polygamy was reinstated after the manner of Abraham, Isaac, and Jacob. But the characteristic Anabaptist communities—as well as the Socinians in Poland—repudiated social revolution and the extreme of Münster, preaching instead sobriety, monogamy, poverty, withdrawal from the world, and pacifism. Anabaptist communities, such as the

Menonites and Hutterites, survive to this day, aloof from bourgeois civilization, in the United States, Canada, and Paraguay. The Diggers and the Levellers in the "left wing" of the Puritan Revolution in England provide another example of the primitivist ethic of Reformation Christianity operating as a social doctrine.

Cultural primitivism was one of the central ideas informing the 18th-century Romantic movement. The Romantic cult of nature and revolt against civilization is stated above all in the works of the marquis de Sade (for whom nature was the ultimate court of appeal) and Jean Jacques Rousseau, following earlier hints in Montesquieu and Diderot. Rousseau's *Émile*, the *Confessions*, and the *Dreams of a Solitary Walker* reject civilization as repressive and enslaving, and equate the primitive, the childlike, and the spontaneous; they suspect the intellect, and praise the noble savage. Many writer-critics of civilization followed, among them Chateaubriand, Théophile Gautier, and Charles Baudelaire.

In Germany, beginning with J. J. Winckelmann's rediscovery of Greek art and architecture in the middle of the 18th century, most writers see the perfect society in that of the ancient Greeks, and some (Winckelmann, Lessing, Herder, Goethe, Schiller, Hölderlin) declare that a new golden age might arise if artists and poets would but imitate the Greeks. The poet Novalis, inspired by a wish to abolish the Christian notions of sin and history, is nostalgic both for the golden age of childhood and for Greek and Oriental antiquity. Similar views figure in the 19th-century poets Kleist and Heine and the philosopher Nietzsche, in the 20th-century poet Stefan George and the novelist Thomas Mann.

Literary primitivism in England and America is mainly cultural. There is less appeal to some ancient or primitive culture, but the same rejection of reason in favor of feeling, the equation of science with disenchantment, and the cult of rural innocence. Wordsworth, Southey, Coleridge, Shelley, and Byron reveal primitivist themes in their work. Wordsworth found his arcadia in the English Lake District, but became progressively disillusioned with primitivist ideals. Coleridge took opium to free his creativity from the bonds of the intellect and dreamed, with Southey, of founding an ideal community in America on the banks of the Susquehanna. The assumptions of cultural primitivism also underlie much of 19th-century American literature up to Henry James.

Primitivism has also left its mark on the social sciences, ever since Rousseau and Herder drew the parallel between the primitive in history and the childlike. Anthropology and the study of primitive religion, which developed in the 19th century (Sir James George Frazer's *The Golden Bough*, J. J. Atkinson, Sir Edward Lubbock, Tylor, Robertson Smith), are evolutionist in temper, but assume the romantic equation of the primitive and the childlike. This same identification influenced the founder of psychoanalysis, Sigmund Freud, who saw neurosis as a form of behaviour similar to that of primitives and children; his technique of treatment cultivates the primitivist value of spontaneity, but his therapeutic goal—an increase in self-consciousness—is antiprimitivist.

A less ambivalent form of cultural primitivism marks much of 20th-century literature, painting, and music. In literature, the works of the Englishman D. H. Lawrence, the American Gertrude Stein, and the Frenchmen Alfred Jarry and Antonin Artaud exalt the primitive and irrational. In painting, the strong influence of African art (reflected in the work of Pablo Picasso, André Derain, and others) was succeeded by an interest in the art of children and the insane (cf. Paul Klee, Jean Dubuffet). Similarly, certain compositions of Claude Debussy, Igor Stravinsky, Darius Milhaud, and Heitor Villa-Lobos are influenced by an ideal of the primitive as against the classical.

PRIMO DE RIVERA, JOSÉ ANTONIO, MARQUÉS DE ESTELLA (1903–1936). Spanish political leader, the founder of the Falange, born in Madrid on April 24, 1903, the eldest son of Gen.

Miguel Primo de Rivera (q.v.). After a brilliant university course and military service, he began a career as a lawyer in 1925. On Oct. 29, 1933, he launched the Falange Española (see *FALANGE*) as a movement committed to overthrowing the government by violence if an antichristian Popular Front should impose itself in a fashion clearly contrary to "the eternal destinies of Spain." His periodicals, *F. E.* (1934) and *Arriba* (1935), were suppressed after fierce polemics; but he addressed meetings up and down the country and expounded his ideas in notable speeches in the Cortes, to which he had been elected in 1933.

Shortly after losing his seat in 1936, José Antonio was arrested. While in prison, he was reelected for Cuenca, but his candidature was annulled by the Popular Front government, which proceeded to dissolve his party. A summary trial ended in a verdict imposed by the government; sentenced to death on Nov. 18, 1936, he was shot in the prison of Alicante on Nov. 20.

In 1939, after Franco's victory, José Antonio's remains were carried shoulder-high across Spain to the Escorial. They were transferred in 1959 to the place of honour in the monument for the dead of the civil war in the Sierra de Guadarrama. His *Obras completas* (articles and speeches) were published in 1944.

(T. F. Bu.)

PRIMO DE RIVERA, MIGUEL, MARQUÉS DE ESTELLA (1870–1930), Spanish army officer and statesman, dictator from 1923 to 1930, was born in Cádiz on Jan. 8, 1870. Having been trained in the General Military Academy in Madrid, he served with the army in Morocco, in Cuba, and in the Philippines between 1893 and 1898. A colonel in 1908, he saw further service in Morocco before being appointed military governor of Cádiz in 1915. He was removed from that office in 1917 (after advocating the exchange of Gibraltar for Ceuta), but was nevertheless promoted lieutenant general in 1919 and appointed captain general of Valencia. For a short period subsequently he was in command of the Madrid infantry division. Next, in 1922, he was appointed captain general of Barcelona, with the task of ending the reign of anarchy in Catalonia. He soon reaped a measure of success; but he saw not only the chaos in Catalonia but also the critical situation of Spain as products of the inefficiency of the parliamentary regime.

BY COURTESY OF THE MINISTRY OF INFORMATION AND TOURISM, MADRID

MIGUEL PRIMO DE RIVERA

Having already gone to Madrid in an attempt to change the government in June 1923, Primo de Rivera on the following Sept. 13 issued a manifesto proclaiming the suspension of the constitution and the establishment of a provisional military directorate. By accepting the *pronunciamiento* King Alfonso XIII linked the future of the throne with Primo de Rivera's dictatorship, which remained effective after the latter had replaced the directorate with a cabinet mainly composed of civilians under his leadership (Dec. 3, 1925). His subsequent life is part of the history of Spain (q.v.) till Jan. 28, 1930, when he resigned power. He then retired to France, where he died, in Paris, on March 16, 1930.

PRIMOGENITURE, a term used to signify the preference in inheritance that is given by law, custom, or usage to the eldest son and his issue, or in exceptional cases to the line of the eldest daughter. In England, primogeniture constituted the rule of intestate succession to land until 1925. See *INHERITANCE: Divided and Undivided Inheritance (Primogeniture)*. See also references under "Primogeniture" in the Index.

PRIMORSKI KRAI (or Maritime Territory) of the Russian Soviet Federated Socialist Republic, U.S.S.R., was created in 1938. Area 64,054 sq.mi. (165,900 sq.km.). Pop. (1959) 1,351,018. The *krai* forms the southern part of the Soviet far east.

between the Sea of Japan and Manchuria. The greater part of its area is taken up by the rugged mountains of the Sikhote-Alin, running northeast-southwest along the coast and rising to 6,086 ft. (1,855 m.) in Mt. Oblachnaya. The mountains drop steeply to the sea and in only a few places is the coastal plain well developed. The only important lowland is the Ussuri Valley along the west of the *krai*, the Ussuri River forming the frontier with China. In the upper Ussuri Valley is the large Lake Khanka. The Sikhote-Alin Range is cut up by the valleys of the large tributaries of the Ussuri, the Bikin, Iman, Vaku, Ulukhe, and Daubikhe and by the shorter streams flowing east to the sea. The climate is of the cold monsoon type, with bitterly cold, dry winters. Vladivostok has a January average temperature of 6° F (−14° C) and farther from the sea conditions are still more severe; e.g., Ussurisk, −3° F (−19° C). Summers, with the onshore monsoon, are wet and cool. Rainfall, about 24 in. (61 cm.) a year in the lowland, rises to over 40 in. (102 cm.) on the mountains. Only the sheltered Ussuri Valley is less rigorous. The Sikhote-Alin is covered by dense coniferous forest, chiefly of fir and pine. Below this is a luxuriant deciduous forest, containing numerous tree species, including Mongolian oak and Amur cork, shrubs, and giant vines. In the southern part of the *krai* lotus and giant water lilies are found.

The inhabitants, although predominantly of Russian and Ukrainian settler origin, include small numbers of primitive Tungus-Manchurian tribes: Golds (Nanaiti), Orochis, Udekheitsy, and Tazy. Of the 1959 population 67% (928,303) were urban, and this high proportion was increasing (in 1961, 71%). Growing urbanization is indicated by the presence of only 9 towns but 45 urban districts. The largest towns are the administrative centre of Vladivostok (290,608), Ussurisk (formerly Voroshilov; 104,310), the port of Nakhodka (63,725), and the coal-mining town of Artem (55,531). Agriculture is important only in the Ussuri Valley, one of the chief soy bean regions of the U.S.S.R. Soy beans occupy over one-fifth of the arable land, while wheat takes another fifth. Oats, maize (corn, chiefly for fodder), barley, rye, and vegetables are also grown. Rice is grown in the south. All around the coasts fishing is a major part of the economy and includes coastal crab fishing, deep-sea fishing, and Antarctic whaling. There are several small coal and lignite fields in the south of the *krai* around Ussurisk and Artem. In the Tetyukhe Region of the Sikhote-Alin tin, lead, and zinc are mined, and iron ore is exploited at Olga on the coast. The great forest resources are the basis of a rapidly developing timber industry in most of the inland urban centres. Bear, lynx, panther, sable, and squirrel are hunted for furs.

(R. A. F.)

PRIMROSE, common name for the genus *Primula*, containing about 500 species distributed throughout the cooler parts of Europe and Asia, and found also on the mountains of Ethiopia and Java; a few are American. They are herbaceous perennials, with a permanent rootstock from which arise tufts of leaves and flower stems, which die down in winter; the new growths formed in autumn remain in a budlike condition ready to develop in spring. They form the typical genus of the primrose family (Primulaceae; q.v.), the floral conformation of which is very interesting botanically.

The variation in the length of the stamens and of the style in the flowers of *Primula* has attracted much attention since Charles Darwin investigated them. Some of the flowers have short stamens and a long style, while others have long stamens or stamens inserted so high up that the anthers protrude beyond the corolla tube, and a short style. Gardeners and florists had for centuries been familiar with these variations, calling the flowers from which the anthers protruded "thrum-eyed" and those in which the stigma appeared in the mouth of the tube "pin-eyed."

Darwin showed by experiment that the most perfect degree of fertility, as shown by the greatest number of seeds and the healthiest seedlings, was attained when the pollen from a short-stamened flower was transferred to the stigma of a short-styled flower, or when the pollen from the long stamens was applied to the long style. Since in any given flower the stamens are short (or low down in the flower tube) and the style long, or conversely, it fol-

JOHN MARKHAM

COMMON PRIMROSE (*PRIMULA VULGARIS*)

lows that to insure a high degree of fertility cross fertilization must occur, and this is effected by the transfer of the pollen from one flower to another by insects. Incomplete fertility arises when the stigma is impregnated by the pollen from the same flower. The size of the pollen grains and the texture of the stigma are different in the two forms of flower.

The best-known species are the common primrose (*Primula vulgaris*), a European perennial with basal, wrinkled leaves and prevailingly yellow flowers—some are purple or blue—but now found in many varietal colours; the cowslip (*P. veris*), also with basal leaves and a long-stalked flower stem bearing a cluster of generally yellow flowers with a dark-coloured eye at the centre and scalelike folds at the mouth; and the oxlip (*P. elatior*), similar to the cowslip, but without the folds at the flower's mouth. All of these are found wild in Great Britain and elsewhere and are widely cultivated, especially in the fine horticultural varieties of polyanthus primroses, which bear profuse clusters of flowers and occur in many colours. The above plants are cool-loving sorts that grow well in heavy soils in slight shade; sloping land (especially an eastern exposure), quite moist in summer but with good drainage, is an ideal situation. In the U.S., about 15 species are native in the region of Oregon and Washington.

The auricula (q.v.) of the garden is derived from *P. auricula*, a yellow-flowered species, native of the Alps and the easiest of all the primroses to grow. The Himalayas are rich in species of primrose, often difficult of determination or limitation, certain forms being peculiar to particular valleys. Of these *P. denticulata*, *stuarti*, *sikkimensis*, *nivalis* and *floribunda* may be mentioned as frequently cultivated, as well as the lovely rose-coloured species *P. rosea*. The royal cowslip (*P. imperialis*) resembles *P. japonica* (see below) but has leaves measuring 18 in. (45.7 cm.) long by 5 in. (12.7 cm.) wide. It grows at an elevation of 9,000 ft. (2,743 m.) in Java and has deep-yellow or orange flowers. Several small-growing hardy species, among which are the choice alpine varieties, afford fine rock garden displays in cool locales; they must be placed where they are secure from excessive dampness during the winter and excessive sunlight in the summer.

One of the most popular of winter and early spring decorative plants is the Chinese primrose (*Primula sinensis*), of which some superb strains have been obtained. *P. japonica*, a bold-growing and very beautiful Japanese plant, is hardy in sheltered positions in England but must be grown in the cool greenhouse over most of the U.S. *Primula cortusoides* of Siberia and *P. sieboldi* of Japan, of which there are many lovely forms, are suitable for outdoor culture and under glass. Many of these are beautiful potted plants of the florist trade. Among the greenhouse primroses, *P. obconica* has hairy leaves which may cause a skin rash in susceptible persons. Two other Chinese species, *P. forrestii* and *P.*

bulleyana, orange-yellow flowered, 2½ to 3 ft. (91 cm.) in height, are hardy in favoured spots in the rock garden.

Cultivated primroses may be found in a considerable variety of colours, ranging from the palest yellow to deep crimson and blue. Most hardy sorts may be propagated by seed sown indoors in early spring; seedlings, kept cool and moist in moderate shade, should be transplanted a few times until they are set in the permanent spot in the garden in early autumn. A light mulch will give adequate protection in the winter. Since primroses do not reproduce true to seed, special varieties may be increased by the division of crowns in early autumn.

Evening primrose belongs to the genus *Oenothera* (q.v.), of the evening primrose family (Onagraceae). The Cape primrose comprises hybrid forms of *Streptocarpus*, a South African genus belonging to the family Gesneriaceae. The Arabian primrose is *Arnebia cornuta*, of the borage family (Boraginaceae), a garden annual. (N. Tr.)

PRIMULACEAE, the primrose family of herbaceous plants, belonging to the order Primales and containing about 800 species in 25 genera (the genus *Primula* has nearly 500 species). The family is cosmopolitan in distribution, but the majority of the species are confined to the temperate and colder parts of the Northern Hemisphere and many are arctic or alpine.

All the members are herbs, sometimes annual, as in scarlet pimpernel (*Anagallis arvensis*); but generally perennial. In *Primula* the plant persists by means of a rhizome and in *Cyclamen* by means of a tuber. The leaves form a basal rosette, as in *Primula* (primrose, cowslip, etc.), or there is a well-developed aerial stem, erect in species of *Lysimachia* (loosestrife), or creeping in *Lysimachia nummularia* (creeping jenny or moneywort). *Hottonia* (water violet) is a floating water plant with submerged leaves cut into fine linear segments.

The leaves are generally simple, often with a toothed margin; their arrangement is mostly opposite or whorled, but may be alternate. The flowers are solitary in the leaf axils, as in scarlet pimpernel, moneywort, etc., or in clusters, as in primrose and cowslip. Each flower is subtended by a bract, and the two first developed sepals stand right and left. The flowers are hermaphrodite, having both stamens and a pistil, and usually have their parts in fives (pentamerous) throughout, though exceptions occur. The sepals are leafy and persistent; the petals are partially joined and form a corolla generally divided into a longer or shorter tube and a limb, which is spreading in primrose, or reflexed in *Cyclamen* and *Dodecatheon*; in *Soldanella* it is bell-shaped; in *Lysimachia* and others the tube is often very short, the petals appearing almost free; in *Coris* and *Omphalogramma* the corolla is irregular; in *Glaux* the petals are absent. The five stamens spring from the corolla tube and are opposite to its lobes; this anomalous position is generally explained by assuming that an outer whorl of stamens opposite the sepals has disappeared, though sometimes represented by scales as in *Samolus* and *Soldanella*. The superior ovary—half-inferior in *Samolus*—bears a simple style ending in a capitate entire stigma, and contains a free-central placenta bearing generally a large number of ovules, which are unusual in having two integuments. The fruit is a capsule, splitting by five, sometimes ten, teeth or valves, or sometimes transversely (a pyxidium) as in *Anagallis*.

Cross-pollination is often favoured by the presence of two structural types of the flower, as shown in species of *Primula*. The two forms have long and short styles respectively, the stamens occupying corresponding positions halfway down or at the mouth of the corolla tube. The pollen grains are also dimorphic and their size corresponds with differences of the stigmatic surfaces of reciprocal flowers (see PRIMROSE). Basic to these morphological differences the plants exhibit a certain amount of genetic self-incompatibility.

The family can be divided into five tribes by characters of the corolla, ovary, and capsule, and by the presence or absence of tubers. On the basis of flower and ovary characters, the family is considered to be allied to the pink family (Caryophyllaceae).

The chief British genera are *Primula*, *Lysimachia* (loosestrifes), and *Anagallis*. The principal American genera are *Primula*,

Samolus (water pimpernels or brookweeds), *Lysimachia*, and *Dodecatheon* (shooting stars or American cowslips). In cultivation the chief genera are *Primula*, *Cyclamen*, *Androsace*, *Omphalogramma*, and *Lysimachia*.

See F. Pax and R. Knuth, "Primulaceae," *Pflanzenreich* 22, iv, 237: 1-386 (1905). (P. S. Gr.; X.)

PRINCE, MORTON (1854-1929), U.S. psychologist and physician, formulated such concepts as neurograms (the neurological record of psychological behaviour) and the coconscious (a parallel, possibly rival, well-organized system of awarenesses comparable with ordinary consciousness). He was born in Boston, Mass., Dec. 21, 1854, and was educated at Harvard University (B.A., 1875; M.D., 1879) with subsequent study at Vienna, Strasbourg, Paris, and Nancy. He recognized motivational forces of emotional conflict but disagreed with Sigmund Freud's insistence on a fundamental underlying theme of sexuality. He was an early user of hypnosis as an exploratory agent and for reeducational therapy.

In addition to studying and teaching abnormal psychology at Harvard, Prince practised medicine, was president of both the American Neurological and the American Psychopathological associations and founded (1906) and edited (1906-29) the *Journal of Abnormal Psychology*. He died Aug. 31, 1929.

He was the author of six books, the best known of which was his study of a multiple personality, *Dissociation of a Personality* (1906). Among others were *The Nature of Mind and Human Automatism* (1885), *The Unconscious* (1913), and *Clinical and Experimental Studies in Personality* (1929).

See H. A. Murray, "Morton Prince," *Journal of Abnormal and Social Psychology*, vol. 52 (May 1956). (M. H. En.)

PRINCE, a title of rank, the various uses of which have led to much misunderstanding. It may imply (1) complete sovereignty; (2) sovereignty all but complete; (3) membership in a family whose head is a sovereign or formerly sovereign prince; or (4) some noble dignity inferior to that of duke.

The word is derived from Latin *princeps* (plural *principes*) which etymologically means simply "the first" or "the leader." Thus in the Roman Republic the senator whose name stood first on the censor's list was called *princeps Senatus*, or leader of the House; and the young men of noble birth who, apparently, led the Roman cavalry in early times (see EQUITES) were *principes juventutis*, leaders of the youth. By the end of the republic, however, *principes* had come to mean "the leading man in the state." In this sense it was adopted by Augustus as an unofficial title in preference to the more military *imperator* (see EMPEROR). Hence the Roman imperial regime from Augustus to Diocletian is often called the Principate. The emperor was also in fact *princeps Senatus*. Augustus also revived the ceremonial parade of the *equites*, and his grandsons Gaius and Lucius Caesar were proclaimed *principes juventutis*. Younger relatives of several later emperors received the same title, which virtually designated an intended successor. Even so, *principes* could still mean "leading men" generally.

The ambiguity of the use of the term prince passed from the Western Roman Empire to the states that took its place.

France.—During the Carolingian period feudalism (q.v.) in France was gradually changed from a system in which vassals were in fact dependent on the king into one in which their dependence was very often an empty formality. The dukes or counts who profited most from this development sometimes usurped the sovereign's title of prince as well as his prerogatives in matters of government; and the masses of territory over which they established hereditary rule—Normandy, Flanders, Champagne, ducal Burgundy, Toulouse (Languedoc), and Aquitaine, for instance—were conventionally designated as "principalities."

Prince, however, was still not an official title of the nobility, and for centuries the sons of the royal house had it only as a description, being ranked instead among the peers of France (see PEERAGE) with the title of duke or count according to the territories granted to them. In the middle of the 15th century, however, members of the royal house came to be distinguished as "princes of the blood" (*princes du sang*), with precedence over

the other peers except at the coronation of the king or in the *parlement*. It was only in 1576 that the princes of the blood who were also peers obtained precedence everywhere over the other peers; and only in 1711 that princes of the blood obtained such precedence absolutely, whether they were peers or not.

By the 16th century the great feudal "principalities" had been broken by the monarchy, and French influence was expanding over territories dependent on the Holy Roman Empire. Members of the ruling dynasties of these territories, for example Lorraine and Savoy, who had peerages in France came to enjoy in France special courtly privileges attached to the rank of *prince étranger*, or "foreign prince." The lords of Monaco had the title of prince from the mid-17th century.

There were also 30 or more "principalities" indistinguishable from petty lordships. In a few cases the king accorded or acknowledged the title without defining the status of a principality in relation to a duchy, a countship or a marquise. Such princely titles were often borne by the eldest sons of dukes.

Germany.—On the decline of the Carolingian monarchy in Germany the so-called stem duchies or dukedoms of the Saxons, Bavarians, Franconians, Swabians, etc., were the counterpart of the great "principalities" of France insofar as they challenged the royal power. In the 10th–12th centuries, however, a new class of *Fürsten* (singular *Fürst*, prince) arose, consisting of the holders of well-defined territorial lordships in immediate dependence on the king and on the *Reich*; and with the disintegration of the stem duchies an Estate of Princes of the Realm (*Reichsfürstenstand*) came into being from the 1180s. This Estate comprised both secular and ecclesiastical princes: on the one hand dukes, counts palatine, margraves, and landgraves, but not ordinary counts (though from the latter part of the 14th century *gefürstete Grafen*, or 'counts ranked as princes,' appear); and on the other archbishops, bishops, certain abbots, and the masters of the military-religious orders. New admissions to this Estate required not only the sovereigns' bestowal of the title *Fürst* (lower than that of duke or landgrave) but also the consent of the existing princes. In the *Reichstag* or Diet (*q.v.*) the *Kurfürsten* or electoral princes (see *ELECTORS*) eventually set themselves apart from the others, whose number grew considerably till the dissolution of the Holy Roman Empire. See *GERMANY: History*, subsections *Fall of Henry the Lion and the Estate of Princes and Emperor and Empire After 1648*.

For the position of the demoted *Reichsfürsten* after 1806 see *MEDIATIZATION*. Of the simple *Fürstentümer*, only ten were not mediatised by 1815—including Liechtenstein, which even survived World Wars I and II. The title of *Fürst* as bestowed by the Prussian monarchy in the 19th–20th centuries was simply honorific.

The German language uses the term *Fürst* for a prince with sovereign or quasi-sovereign rights or for the head of a princely family, but may use *Prinz* for a junior member of a sovereign or princely house. Examples are *Kronprinz*, crown prince; *Kurprinz*, electoral prince, heir to an electorate; *Erbprinz*, hereditary prince, heir to a principality; *Prinz von Preussen*, heir presumptive to Prussia; *Prinz von Battenberg*, for descendants of the grand ducal house of Hesse through a morganatic marriage (*q.v.*).

Spain and Portugal.—In Spain counts of Barcelona (*q.v.*) had been regarded as princes of Catalonia in the sense that they were the greatest feudatories of that country; and when Count Ramon Berenguer IV became king-consort of Aragon in 1137 he styled himself prince of Aragon instead of king. The sons of Spanish kings, meanwhile, had the style of infante; but the title of prince of Asturias was created, in 1388, for the eldest son of John I of Castile, namely the future Henry III of Castile. On the union of the Castilian and Aragonese crowns this title became that of the heir apparent to the whole Spanish monarchy; it long remained the only Spanish princely title. In 1795, however, the title prince de la Paz was created for Manuel de Godoy, with higher rank than his duchy of La Alcudia; but it was abolished in 1808. Baldomero Espartero received the title prince de Vergara in 1872 for his lifetime only. Outside Spain, on the other hand, the Spanish kings bestowed princely titles with extreme liberality.

In Portugal the heir apparent to the throne had the title of

prince royal from the reign of King Edward (Duarte).

Italy.—In southern Italy the Lombard dukes of Benevento became practically sovereign princes after the Frankish annexation of the northern kingdom of Lombardy (774); and successive partitions of their territory, from 847, created three principalities, Benevento, Salerno, and Capua. In the 11th century the latter two fell to the Normans (see *NAPLES, KINGDOM OF*), while Benevento became an exclave of the Papal State. Subsequently, princely titles became very numerous in southern Italy: the Spanish kings conceded at least 120 for Sicily and about as many for Naples. For Italy as a whole the aggregate was increased by Roman principalities created by the papacy and by principalities of the Holy Roman Empire in the north.

Eastern Europe and the Levant.—In Russia and in Poland the title prince (Russian *kniaz*, Polish *książę*) was accorded to descendants of sovereign or formerly sovereign dynasties, whether Russian, Tatar, Lithuanian, or Polish. For grand princes see *GRAND DUKE*. Apart from this use, the title was granted as a high rank of nobility by the Russians from Peter the Great's time. In Poland, where ten princely houses claimed descent from ancient dynasties, there were four more created by the Holy Roman Empire and one created by the Holy See, as well as one created in 1808 by the Russians, but only two created for ordinary nobles by the Polish crown (Poniatowski in 1764, Poninski in 1773).

The Frankish principality of Achaia (Achaia), established in 1205 (see *GREECE: History*), disappeared with Turkish conquest in 1456–58; but later the rulers of some Christian countries under the real or nominal suzerainty of the Turkish sultans were styled princes. Such were the rulers of Transylvania in the 16th–17th centuries; those of Moldavia and Wallachia under the Phanariote regime (whence some Phanariote families conserve the princely title) and their successors, princes of Rumania, from 1866 to 1881; those of Serbia from 1815 to 1882; those of Bulgaria from 1878 to 1908; and also those of Samos from 1832 to 1913.

The principality of Antioch (see *CRUSADES*) may have been so designated either because of traditions imported by the Normans from southern Italy or because of its controversial relationship to the Byzantine empire, which claimed suzerainty over it.

Great Britain.—In Great Britain the word "prince" can be used in a descriptive way for a sovereign or a magnate (dukes, marquesses, and earls may be so described in their formal style); but as a title of rank it is confined to members of the royal family.

The Anglo-Saxon word *aetheling* survived into the 12th century as a designation of the sons of kings; and Henry III's son was known as simply "the lord Edward" before he became king as Edward I (1272). The indigenous rulers of Wales, however, who had been kings till the 11th century, were thereafter styled princes (*tywysog*); and it was to conciliate the conquered Welsh that Edward I, in 1301, invested his son, the future Edward II, as prince of Wales. From Edward III's time the king's eldest son was usually invested in due course as prince of Wales, but this title had always to be granted anew by the sovereign, who had merged it with the crown on his accession. The king's younger children, meanwhile, were "but gentlemen by birth and called after their names, as Lord Henrie or Lord Edward" (William Harrison, *Description of England*, 1577) till in James I's reign the title "prince" was extended to all sons of the sovereign. As late as Charles II's time the nieces of the king, both of whom later became queens regnant, were called simply the lady Mary and the lady Anne.

From George I's accession (1714) it became settled practice for the sovereign's descendants in the male line (*i.e.*, his children, and the children of his sons) to be styled "prince" and "royal highness"; great-grandchildren in the male line were "prince" and "highness." In 1917 George V limited the title of prince to the sovereign's children and the children of the sovereign's sons; the only extension was for the eldest living son of the eldest son of the prince of Wales. Thus other great-grandchildren in the male line would merely have the courtesy titles of the children of dukes (see *ADDRESS, FORMS OF*), and their children, apart from the eldest son when he inherited the dukedom, would have no title whatsoever. The granting or withholding of a princely title remained, however, a matter of the sovereign's will: Elizabeth II's consort,

Philip, duke of Edinburgh, was expressly created a prince of Great Britain and Northern Ireland in 1957.

PRINCE ALBERT, a city in the province of Saskatchewan, Can., is on the North Saskatchewan river 220 mi. N. of Regina, near the central northern extremity of the settled part of the province. Founded in 1866 as an Anglican mission station, near the site of a fur trade post established in 1776, it became a centre for the lumbering industry in the early 1900s. Now Saskatchewan's northern "capital," it serves a large agricultural and forest region and a vast northern hinterland. It is a northern provincial government headquarters and has good railroad, highway and air services, a television and radio station and a daily newspaper. It is the site of a federal penitentiary. Its industries include an oil refinery, wood preserving plants, a plywood plant, woodworking shops and a packing plant. Pop. (1961) 24,168. (C. S. Br.)

PRINCE EDWARD ISLAND, in the gulf of St. Lawrence, is the smallest province of Canada. The arc of the crescent-shaped island roughly parallels the curving southern shore of the gulf; it is separated from the mainland by Northumberland strait, which has a maximum width of 25 mi. (40 km.). The province has less than 1% of the population and area of Canada and plays a very minor role in the economy and politics of the country. Yet "the island" is cherished by thousands of its former residents and their families, widely scattered over North America. The almost feudal system in which its lands were held for nearly a century makes its history of unique interest; and L. M. Montgomery's *Anne of Green Gables* made its national park, which enshrines a near replica of "Green Gables," a tourist mecca.

Size, Shape and Location.—The curving island has a maximum length of 145 mi. (233 km.). From a maximum width of 34 mi. (55 km.), it narrows to isthmuses which in two places, north-east of Charlottetown (the capital) and near Summerside (the other town), are less than 3 mi. (5 km.) from tidewater to tide-water. The three lobes thus pinched off roughly correspond to the three counties, from east to west, Kings, Queens and Prince. The land area is 2,184 sq.mi. (5,657 sq.km.).

Physical Geography.—The bedrock, well covered by dune sand on the gulf shore and glacial ground moraine elsewhere, is exposed in low cliffs on the eastern and southern shores. An unusually uniform red sandstone, it does grade off both to sandy siltstones and shales and coarser conglomerates. The age of the formation is thought to be Permian (235,000,000 years). The apparently horizontal strata actually dip toward the northeast and must be younger than similar beds exposed on the mainland to the south. The dip and cliffing suggest the remnants of an old cuesta, elsewhere dismembered or drowned beneath the waters of the gulf. In this soft sandstone block stream erosion has carved a gently rolling plain grading to rougher hills of over 400 ft. (120 m.) elevation west of Charlottetown and to some few stretches really flat to the eye west of Malpeque bay. The intricate serration of the shore line with many deep estuaries brings sea and land into intimate relation; no point of the island is more than 10 mi. (16 km.) from tidewater.

The soils, everywhere developed from the thick mantle of glacial drift, tend to be coarse-textured sandy loams. There are more clayey phases and a good deal of swamp and bog; at the other extreme are the dunes that line much of the northern shore. The soils are strongly acid podsols, rather low in plant nutrients.

As elsewhere in the Atlantic provinces and New England states the weather is markedly variable; the island lies on one of the most heavily traveled storm tracks in North America. There is much sunshine but, on the average, every third day has some precipitation; the annual 40 in. (100 cm.) normally includes 9 or 10 ft. (3 m.) of winter snow. An occasional dry summer month and extremes of open, or deeply snowbound, winters point up the variability. Monthly temperature means lie between February's 17° F (about -8° C) and July figures in the upper 60s (about 20° C); the effect of the sea is seen in a long, laggard, chilly spring and in a late, warm and truly glorious autumn.

When Jacques Cartier visited the island in 1534 it was covered with a dense mixed forest, its trees of both boreal coniferous and northern hardwood types. There is a good deal of tree cover,

predominantly spruce, on farm woodlots but the 16th-century forest has disappeared. With it have gone most of the larger animals (bear, moose, caribou, deer, seals, walrus and even beaver, but smaller animals and a wide variety of birds, including migratory ducks and geese, are still plentiful as are the fish and shellfish (cod, hake, halibut, herring, alewife, trout, salmon, eels, lobsters and clams) of its streams, estuaries and offshore coastal banks.

History.—Cartier was the first European of record to visit the island. Afterward it was largely ignored by the French until the 18th century, although, much earlier, it acquired the name Île St. Jean (St. John's Island) which it was to retain until 1798 when its present name was chosen (after that duke of Kent whose daughter was to become Queen Victoria).

It received more attention from the French, as an adjunct of Louisbourg on Île Royale (Cape Breton) and a refuge for Acadians from the mainland, especially after the treaty of Utrecht, and when Lord Rollo invested it for the British in 1758 it may have held as many as 5,000 settlers, mostly Acadian. Most of these were deported and the island was surveyed and divided into 3 counties, each with a townsite and "royalty," 14 parishes and 67 lots or townships. These were then awarded, by lot, to upward of 100 applicants for royal favour (Scots predominated) under conditions which should have guaranteed rapid settlement. The grantees (proprietors) did little, however, and by 1800 there were scarcely more settlers than in the 1750s. But the few Highland Scots, American Loyalists and remaining Acadians of the turn of the century were soon joined by thousands of others, dominantly Highlanders and southern Irish and, as the tenant farmers slowly won representative and responsible government (the colony was separated from Nova Scotia in 1769), pressure was increased on the often absentee proprietors to open their lands and the freehold was gradually enlarged. By 1873 only the most recalcitrant of the landlords remained to be bought out.

The little colony joined the new dominion six years late and rather reluctantly; it has been said to have been "bought" into confederation by Canada's assumption of its overwhelming railway debt, promises of better communications across the strait and a large subsidy to take care of the extensive land purchases from the proprietors. Since then it has been ever in the forefront of moves by the smaller provinces to obtain a larger share of federal revenues to help them support schools and other local services at levels nearer those prevailing in central Canada.

Government.—The form of government is that defined by the British North America act (see CANADA: History). The province at first sent 6 members to the Canadian house of commons; it now sends 4 to a house of 265 and 1 of these is occasionally given a cabinet post, usually minor. It has a local assembly of 30 members elected in pairs (a relic of the period of two houses) from 15 constituencies and the government is organized by the majority party in the usual British parliamentary system.

Population.—The population, roughly 30,000 in 1830, reached 80,000 in 1860 and over 110,000 in the 1880s, when immigration had largely ceased and the outflow of population began. The highest census total was 109,078 in 1891; by 1921 it had dropped below 90,000 but rose to 99,285 in 1956 and to 104,629 in 1961. The

Prince Edward Island: Places of 5,000 or More Population*

Place	Population				
	1961	1956	1951	1941	1931
Total province	104,629	99,285	98,429	95,047	88,617
Charlottetown	18,318	16,707	15,887	14,821	10,811
Summerside	8,611	7,242	6,547	5,034	3,228

*Populations reflect data as each place was constituted at date of each census.

great tide of emigration affected chiefly descendants of Scots and Irish. A population over half Scots and one-fourth Irish (and about 10% Acadian) in the 1860s had changed to about 30% each of Scots and English (in claimed ultimate origin), about 20% Irish and something under 20% Acadian by the 1960s. Other elements in the population are negligible; only a handful of Micmac Indians remain.

The population density is over 47 per square mile but more

than one-fourth of the people live in the city (Charlottetown) and town (Summerside) and the rural population is much denser west of Charlottetown than in the east. "Farm" population has been declining even more rapidly than "rural" population; it numbered 34,514 in 1961.

Education and Religion.—Public primary and regional high schools provide education to the tenth grade. Four more years of schooling are available at Prince of Wales college (founded 1860) in Charlottetown (also the principal teacher-training centre), through the second year of a university course. Full collegiate education is offered by St. Dunstan's University (Roman Catholic, founded 1855), also in Charlottetown. Roman Catholics compose the largest single denomination, with about 46% of the population, divided among those of Acadian, Irish and Highland Scots origin. The Protestant majority is made up chiefly of four groups: United Church 26%, Presbyterian 12%, Anglican 6% and Baptist 5%.

Production.—In 1961 about 33% of the population was classed as agricultural and its farms (averaging over 110 ac.) occupied about two-thirds of the surface (much of the rest of which had been farmed in the 19th century). A mixed livestock-and-crop agriculture received most of its revenue from animal products: sales of cattle, swine and dairy products alone yielded half of it. Potatoes (largely seed), which provided about 15% of the total, was the only cash crop of significance. Tobacco growing was introduced in 1960. Most farms were self-sufficient to a degree, with 17% of all farm production consumed thereon by farmers. More than 19 out of 20 farms were operator-owned. Agriculture accounts for about 33% of the total net value of production.

Fisheries yield about 10% of the total net production. Lobsters, taken in limited seasons, provided two-thirds to three-fourths of that value, cod and related ground fish, herrings, smelts and cysters the rest. Most fishermen and boats were unspecialized; many of the men were part-time farmers.

The island was the birthplace of silver fox farming, for which it was world famous from 1910 to 1940, but after 1950 foxes all but disappeared and the few fur farms left raised chiefly mink. Forest products, derived from indifferently managed farm woodlots, played a steady but minor role in the economy.

The net product of manufacturing industries has comprised about 15% of the total, chiefly from processing industries for agricultural, fishery and forest products; butter and cheese making, meat slaughtering and packing, fish processing and feed milling and mixing predominated. There is an interesting textile industry (bag making for fertilizer and potatoes) and a significant wood-working enterprise although plants are small. The tourist industry, still not strongly developed, offers excellent opportunities if transportation could be improved.

Communications.—The island's railway was begun in 1871 as a narrow-gauge (3 ft. 6 in.) line notable for its curves and grades. The establishment of a car-ferry connection with the mainland (Borden to Cape Tormentine in New Brunswick) during World War I led to a change to standard gauge; by 1960 that service across the strait to and from Charlottetown and Summerside was the chief function it performed. A highway-building program begun in the 1950s greatly increased the mileage of paved roads on the island.

Communication across the strait has been a central problem of island life since the 18th century. Even a supplementary automobile ferry from Wood Islands in the southeast to Caribou (near Pictou, in Nova Scotia) has only widened the bottleneck. Good air connections to Summerside and Charlottetown have relieved the situation somewhat.

PRINCE ISLAND (PRÍNCIPE): see SÃO TOMÉ E PRÍNCIPE.

PRINCES ISLANDS (Turkish, KIZIL ADALAR), in ancient times Demonesi Insulae, a group of nine islands in the Sea of

Marmara about 15 mi. (24 km.) SE of Istanbul forming a district of the province (il) of that city. Area 5.4 sq.mi. (14 sq.km.). The smallest, Sedef Adasi (Antirrobethos or Antirobethos), and the four largest are inhabited, and on Yassi Ada (Plati) there is a branch of the Naval Academy. The four large ones are Buyukada (Prinkipo, ancient Pityoussa); Heybeli Ada (Khalki or Halki, ancient Chalcitis); Burgaz Adasi (Antigoni, ancient Panormos); and Kinali Ada (Proti). Winter population (1960) 19,834; summer population approximately 140,000.

In ancient times copper, known as *demonios chalkos*, was mined there. The monasteries built during the Byzantine period figured largely as places of exile. The empresses Irene (widow of Leo IV) and the Macedonian Zoe were sent to Prinkipo; the emperors Philippicus Bardanes, Michael I Rangabe, Romanus I Lecapenus, and Romanus IV Diogenes retired to Proti and the anti-iconoclastic patriarch Methodius to Antigoni. The only surviving Byzantine buildings are the chapel of St. John the Baptist on Antigoni, said to have been built by the empress Theodora, part of which dates from the time of Methodius, and the chapel of the Theotokos on Khalki built by Maria Comnena. The monastery of St. John (later of the Theotokos) beside it was rebuilt by her husband John VIII Palaeologus and again rebuilt in about 1680, and in the 18th century by Alexander Ypsilanti, hospodar of Moldavia; it was used after 1831 by the Greek Commercial School and later by the Turkish Naval Academy. Also on Khalki is Hagia Trias, rebuilt in 1844 and housing since then the chief school of theology of the Greek Orthodox Church.

See G. Schlumberger, *Les Îles des Princes*, 2nd ed. (1925). (J. CH.)

PRINCETON, a borough of Mercer county, N.J., U.S., the seat of Princeton university (*q.v.*), is located midway between New York city and Philadelphia. Capt. Henry Greenland established a plantation on the site of the present village in 1681 and 15 years later a number of Quaker families settled in the area. During the colonial period, because of its location, Princeton was the principal luncheon stop for stagecoach passengers traveling between Philadelphia and New York. In the pre-Revolutionary period the College of New Jersey, now Princeton university, became a centre of anti-British feeling; John Witherspoon, its president, Richard Stockton, a resident of the town, and John Hart, from nearby Hopewell, were three of the five New Jersey men to sign the Declaration of Independence. Nassau hall, principal structure of the college, completed in 1756, changed hands three times in the battle of Princeton and it was within its walls that the engagement ended, with Washington's troops defeating the British under Col. Charles Mawhood on Jan. 3, 1777, following the battle of Trenton. The legislature of the state of New Jersey convened in Princeton the following summer and the Continental congress was assembled there from June until Nov. 1783.

Educational institutions in Princeton in addition to the university include the Institute for Advanced Study, established in 1930; Princeton Theological seminary, a Presbyterian seminary established in 1812; Westminster Choir college, a private college established in 1926, and its affiliated Columbus Boychoir school; and several distinguished private schools. The Educational Testing Service, with headquarters there, develops and publishes achievement tests used in schools and colleges throughout the nation. Research laboratories operated by industrial firms and non-profit organizations have been attracted to Princeton by the presence of the educational facilities.

In addition to a community of scholars who come from many nations, there reside in Princeton business and professional men and women who commute daily to Newark, New York city, Philadelphia and Trenton. Mid-town Palmer square, a business district, is an outstanding example of urban redevelopment emphasizing colonial architecture.

"Morven" in Princeton is the official executive mansion of the governor of New Jersey. The oldest portion was built in 1701 by Richard Stockton, grandfather of the signer of the Declaration of Independence. Walter E. Edge, then governor, purchased it in 1944 and ten years later presented it to the state. The first occupants under its new function, Gov. and Mrs. Robert B. Meyner, moved into it in 1957.

For comparative population figures *see* table in NEW JERSEY: Population. (E. R. D.)

PRINCETON UNIVERSITY, a privately endowed non-sectarian institution of higher learning for men, at Princeton, N.J., until 1896 called officially the College of New Jersey. Its buildings are grouped in the central portion of a campus of about 2,200 acres. Nassau Hall, the oldest and historically the most interesting building on the campus, was at the time of its completion in 1756 the largest academic building in the American Colonies. Designed by Robert Smith, the architect of Independence Hall in Philadelphia, it was named in honour of William of Nassau, William III of England. There in 1783 George Washington received the formal thanks of the Continental Congress for his conduct of the Revolutionary War.

Characteristic of life at Princeton, in addition to the university's rural location and consequently its active outdoor interests, are the residential dormitory system, the system of elective upper-class eating clubs, and the form of student self-government, illustrated particularly by the honour system, under which undergraduates participate in the administration of university discipline.

The Committee on Admission takes into consideration the entire record of each applicant and endeavours to select those candidates who seem best qualified to gain most from a Princeton education. There are no quotas by schools, or types of schools, or by geographic areas. In the last analysis, admission is based on a comparison of the records of all applicants.

The university offers undergraduate courses in the liberal arts and sciences leading to the degrees of bachelor of arts and bachelor of science in engineering. In addition to the arts and sciences, graduate work leading to the master's and doctor's degrees is also offered in architecture, engineering, and public and international affairs.

Princeton has engaged in a number of pioneering ventures in educational practice, notably the preceptorial method of instruction, introduced in 1905, and the plan of independent study for upperclassmen, introduced in 1923. It has also pioneered in its Woodrow Wilson School of Public and International Affairs in developing men for public life and for professions and businesses related to public affairs, in its School of Engineering and Applied Science in developing engineers who have broad cultural backgrounds as well as technical knowledge, and in its interdepartmental programs of study, a gradual development that culminated in 1953 with the creation of the Council of the Humanities.

Princeton's undergraduate program has as its core an offering of courses in four broad fields of learning—natural science; social science; arts and letters; and history, philosophy, and religion. Such courses are intended to give the student a basic understanding of the discipline of each area. In upper-class years he takes a combination of courses and engages in independent work in a specific field or interdepartmental program.

In assuming the university title in 1896, it was definitely concluded that Princeton's future did not lie in developing professional schools but in upholding pure learning and in devoting itself "to the liberal aspects of those studies which underlie and broaden professional and technical education." The university, therefore, became not a congeries of professional schools overshadowing an undergraduate department but a large, homogeneous, and well-organized body

of undergraduate students, with a small, carefully selected graduate school devoted to the liberal arts and sciences.

History.—The university owes its origin to a movement set on foot by the Presbyterian Synod of Philadelphia in 1739 to establish in the middle colonies a college to rank with Harvard and Yale in New England and with William and Mary in Virginia. As a result of dissension in the church, no progress was made until 1746, when the plan was again broached by the Synod of New York, formed by the secession of the presbytery of New York and the presbytery of New Brunswick, radical (New School) presbyteries of the Synod of Philadelphia. Most of the leaders of the presbytery of New Brunswick had been educated at the so-called Log College, a school with restricted curriculum at Neshaminy, Pa., about 20 mi. from Philadelphia, founded in 1726. The opportunity was taken by the Synod of New York to found a larger institution of higher learning, broader in scope and training, and to transfer to the new project the Log College interests. On Oct. 22, 1746, John Hamilton, acting governor of New Jersey, granted a charter for erecting a college in New Jersey, which was opened in May 1747, at Elizabeth, N.J. A second charter was granted by Gov. Jonathan Belcher, who on his arrival in the province in 1747, had at once taken the college under his patronage. The college was removed to Newark, where the first graduation exercises were held in 1748; but the situation was unsuitable, and in 1752 the trustees voted to remove the college to Princeton. While additional funds were being collected in Great Britain, work was begun in Princeton in 1754 on the first college building, Nassau Hall.

John Witherspoon, president during the Revolutionary period, influenced the college strongly by his personality and political prominence, and graduates of his training became leaders in public affairs. The history of the college during the first half of the 19th century was uneventful. Because of its large Southern clientele, it suffered in the U.S. Civil War a blow from which it recovered only under the energetic administration of Pres. James McCosh (1868–88). The undergraduate enrollment was nearly trebled, gifts amounting to more than \$2,000,000 were contributed, only half of which sum was for endowment, 14 new buildings were erected, and important changes were made in the curriculum.

Fellowships were established in 1869, a limited elective system was introduced in 1870, the John C. Green School of Science was erected in 1873, the graduate department was systematized in 1877, and the faculty grew from 17 to 40 and the number of volumes in the library from 25,000 to 65,000.

BY COURTESY OF PRINCETON UNIVERSITY

NASSAU HALL AT PRINCETON UNIVERSITY

Originally containing the dormitory, refectory, classrooms and chapel, it has served as an administrative building since the early 19th century

Under Pres. Francis L. Patton (1888-1902) a school of electrical engineering was established, the honour system was instituted, the plan of electing alumni trustees was adopted, 17 buildings were erected, the student body was doubled, and the faculty increased to 100, while the endowment reached \$2,500,000. In 1902, Woodrow Wilson, of the class of 1879, was elected president. In his administration the undergraduate curriculum was again revised, the departmental system was organized, and an extensive building program was completed. To obtain the necessary funds, a committee of 50 alumni was formed, later changed into a graduate council. Through their agency in the eight years of President Wilson's administration the university received more than \$4,500,000, the faculty was greatly strengthened, and the library increased to 271,000 volumes. A plan for grouping the undergraduate and graduate students into small self-contained residential units on the so-called quad plan was prematurely proposed by the president in 1907 and was withdrawn by the trustees. The Princeton plan of a residential building for graduate students was successfully tested on a small scale, and a bequest in 1908, although inadequate for the full project which included professorships and fellowships, gave the plan its first semblance of permanent realization. Additional funds being conditionally offered in 1909, controversy developed as to the site for the building and finally as to the plan itself, the president no longer favouring it. A further bequest of about \$2,000,000 for the project brought matters to a head and the president recommended acceptance of the legacy. In September 1910, having received the Democratic nomination for governor of New Jersey, Wilson resigned the presidency.

John Grier Hibben, of the class of 1882, professor of philosophy in the university, was the 14th president of Princeton, serving from January 1912 to June 1932. His administration was marked by extended administrative reorganization, by large additions to the endowment, and by extensive expansion along material and scholastic lines. Faculty autonomy was made complete: a joint committee of trustees and faculty was organized to consider all matters of educational policy and administration; the faculty was given voice in forming its committees and initiating appointments, promotions, and increases of salary; the rights of the individual in cases of dismissal were safeguarded; faculty retirement allowances and insurance were arranged.

In 1913, the erection of the residential Graduate College rendered permanent what had been an experimental feature of the Princeton Graduate School. The School of Architecture was opened in 1920. The School of Engineering, now the School of Engineering and Applied Science, was reorganized and enlarged in 1921, and the School of Public Affairs, now the Woodrow Wilson School of Public and International Affairs, designed to give its students a broad background for an understanding of and active participation in local, state, national, and international affairs, was founded in 1930. Edward Dickinson Duffield of the class of 1892 a trustee of the university, served as acting president from June 1932 until the election of Harold Willis Dodds, professor of politics, as 15th president in June 1933. His long administration of 24 years saw great expansion of the work and facilities of Princeton University. The university commemorated the academic year 1946-47 as its bicentennial anniversary and in 1949 established ten bicentennial preceptorships at the assistant professor level to encourage scholarship and teaching.

In 1951 Princeton established the James Forrestal Research Center in the former 825-acre plant of the Rockefeller Institute for Medical Research, comprising 15 buildings and laboratories. The centre was established for the immediate purpose of permitting the university to expand its program of basic research for national defense, and for the long-term purpose of providing additional laboratories and facilities to meet the more exacting requirements of modern scientific and engineering research.

The many research programs are concerned with problems in aeronautical engineering, aerospace propulsion sciences, biochemistry, applied nuclear sciences, nuclear chemistry, high energy physics, and auditory research (Department of Psychology). Facilities include a 3-Bev proton accelerator, co-sponsored by the University of Pennsylvania and a plasma physics laboratory.

The University Chapel, its stained-glass windows portraying the life, teaching, and influence of Christ, was dedicated in 1928. The Graduate College, the first residential graduate college in the United States, was dedicated in 1913. A new dormitory quadrangle accommodating 275 unmarried graduate students was completed in 1963. Other buildings include: The Dean's House (1756); Stanhope Hall (1803); Joseph Henry House (1837); McCosh Hall (1907); Palmer Physical Laboratory (1908); Guyot Hall (1909); Holder Hall (1910); Palmer Memorial Stadium (1914); Herbert Lowell Dillon Gymnasium (1947); the Harvey S. Firestone Memorial Library (1948); Edward S. Corwin Hall (1953); George M. Moffett Biology Laboratory (1960); the Engineering Quadrangle (1962); the Charles W. Caldwell Field House, Woolworth Center of Musical Studies, and Architecture Building (1963); the Woodrow Wilson School of Public and International Affairs and the Art Museum (1965).

In 1953 the university reemphasized its long interest in the humanities by the establishment of the Council of the Humanities, which has the function of assisting members of the faculty and graduate and undergraduate students in interdisciplinary studies in the area. The council provides senior and junior fellowships for such study and supervises several special programs of instruction in which the broad range of the humanities and the social sciences is brought to bear upon programs of fundamental value or upon the civilizations of particular areas of the world.

In 1956, in order to provide more effective channels of communication with industrial corporations, a program of conferences was established to cover general and specialized problems of common interest to industry, governmental agencies and the faculty in all areas of the university. The conferences are planned and directed by the various departments and attended by faculty and interested corporation officers and government officials.

On July 1, 1957, on the retirement of President Dodds, Robert Francis Goheen of the department of classics became the 16th president of the university. Developments during the first years of his administration included raising faculty salaries and benefits; the establishment of many cross-departmental programs of study; reorganization of the curriculum of the School of Engineering and Applied Science; the development of a strong graduate program in public and international affairs; a sharp increase in the size of the Graduate School; and provisions for advanced placement and standing for gifted undergraduates. Financial support for present and future developments was provided by the successful conclusion in 1962 of a capital gifts campaign that exceeded the \$53,000,000 goal by more than \$7,000,000, to which was added an anonymous foundation gift of \$35,000,000 for the graduate program of the Woodrow Wilson School.

Princeton University Press.—Organized as a nonprofit association, closely affiliated with, but legally independent of, the university, the Princeton University Press was founded in 1905 and incorporated in 1910. In 1912 it published its first book; approximately 60 new titles are published annually.

The broad aim of the Princeton University Press was defined as "the promotion of education and scholarship," and it serves the university by publication and distribution of its research and offers other services to scholars there and elsewhere.

See also references under "Princeton University" in the Index. (J. D. BN.)

PRINCIPAL AND AGENT refers to the law of agency dealing with salesmen, brokers, managers, and other commercial agents having power to make contracts for their employers. This branch of agency came to be treated separately as a result of the great increase in shipping, banking, insurance and other mercantile transactions that occurred during the late 18th and early 19th centuries. See AGENCY.

PRINCIPE ISLAND: see SÃO TOMÉ E PRÍNCIPE.

PRINGLE, SIR JOHN (1707-1782), British physician, the founder of modern military medicine, was born on April 10, 1707, at Stichel, Roxburgh, and educated at St. Andrews, at Edinburgh, and at Leiden. He settled in Edinburgh as a physician, but after 1734 also acted as professor of moral philosophy in the university. In 1742 Pringle became physician to the earl of Stair, then com-

manding the British army in Flanders, and in 1744 was appointed physician general to the forces in the Low Countries. In 1749, having settled in London, he was made physician in ordinary to the duke of Cumberland, and subsequently received other court appointments as physician, being made a baronet in 1766. In November 1772 he was elected president of the Royal Society, but resigned his presidency in 1778. Pringle died on Jan. 18, 1782.

Pringle remedied camp sanitation and the ventilation of hospitals and laid down the principles for preventing dysentery and hospital fever, at the same time showing that the different forms of dysentery were varieties of one disease and that jail fever was the same as hospital fever (i.e., typhus fever). Pringle's chief works are: *Observations on the Nature and Cure of Hospital and Jail Fevers* (1750); "Experiments on Septic and Antiseptic Substances" in the *Philosophical Transactions of the Royal Society* (1750); and especially the *Observations on the Diseases of the Army* (1752). His *Six Discourses* (1783) contains a biography by A. Kippis.

PRINGSHEIM, NATHANAEL (1823–1894), German botanist, who made outstanding contributions to the study of algae, was born in Upper Silesia on Nov. 30, 1823. He studied at the universities of Breslau, Leipzig, and Berlin; graduated in 1848 as doctor of philosophy with a thesis on the form and development of the thickening layers of plant cells; and rapidly became a leader in the great botanical renaissance of the 19th century. His contributions to scientific algology were of striking interest; together with the French investigators G. Thuret and E. Bornet, he ranks as a founder of the scientific knowledge of the algae. Pringsheim was among the first to demonstrate the occurrence of a sexual process in this class of plants, and he drew from his observations general conclusions as to the nature of sexuality. The conjugation of zoospores, regarded by Pringsheim as the primitive form of sexual reproduction, was a discovery of fundamental importance.

A work (1873) on the course of morphological differentiation in the Sphacelariaceae, a family of marine algae, is of great interest, inasmuch as it treats of evolutionary questions; the author's point of view is that of K. W. von Nägeli rather than that of Darwin. Connected with Pringsheim's algological work was his investigation of the Saprolegniaceae, a family of aquatic algalike fungi. His career as a morphologist reached its peak in 1876 with the publication of a memoir on the alternation of generations in thallophytes and mosses.

From 1874 to the close of his life Pringsheim's activity was chiefly directed to plant physiology. He founded the *Jahrbuch für wissenschaftliche Botanik* and the German Botanical Society. His work was, for the most part, carried on in his private laboratory in Berlin; he held a teaching post of importance for only four years, 1864–68, when he was professor at Jena. Pringsheim died in Berlin on Oct. 6, 1894.

He wrote memoirs on *Vaucheria* (1855); the *Oedogoniaceae* (1855–58); the *Coleochaeteae* (1860); *Hydrodictyon* (1861); and *Pandorina* (1869). His complete works were published by his children (*Gesammelte Abhandlungen*, four volumes, 1895–96).

PRINSEP, JAMES (1799–1840), English numismatist and Indologist, whose work on paleography and numismatics shed light on Indian history, was born probably at Troby Priory, Essex, on Aug. 20, 1799. In 1819 he took up an appointment at the Calcutta mint, and was assay master at the Benares mint (1820–30). In 1832 he became assay master and secretary to the mint committee at Calcutta, but ill health forced him to return to England in 1838, and he died in London on April 22, 1840.

As secretary of the Asiatic Society of Bengal (1832–38) and editor of its journal, Prinsep had access to, and developed the study of, the largest collection of Indian coins then existing. His greatest achievement, however, was his brilliant decipherment (1838) of the rock and pillar inscriptions of Asoka (q.v.). This placed the chronology of ancient India on a much firmer basis. Originally trained as an architect, at Benares he designed and built an important bridge over the river dividing Benares and Bihar; restored a mosque; improved the design of the new mint and the city's drainage; and conducted a municipal census. At

Calcutta, he completed the construction of an important canal in the Ganges delta, was responsible for the introduction of a uniform coinage (under which the "company's rupee" was substituted in 1835 for the various coins in use), and reformed the Indian system of weights and measures.

See his *Essays on Indian Antiquities, Historic, Numismatic, and Palaeographic*, with a memoir by H. T. Prinsep, collected and ed. with notes, etc., by E. Thomas, 2 vol. (1858). (A. L. Ba.)

PRINTED CIRCUIT, an electrical circuit in which the usual wiring—and, occasionally, resistance elements—is replaced by patterns of conductive material applied on sheets of ceramic, glass, or laminated or solid plastic. The circuit patterns are produced by photographic and mechanical printing procedures much like those used in the graphic arts.

First developed on a large scale after World War II, the techniques for producing printed circuits helped meet the demands of industry for more efficient mass production of electrical equipment. The increasing application of electronic equipment in business and industry during the postwar years created problems of weight, size, reliability and production cost. Most of these problems were solved to a large extent, particularly in the radio and television industries in the United States, by the use of printed circuits.

BY COURTESY OF DELCO RADIO DIV., G.M.C.

(LEFT) COMPONENT SIDE AND (RIGHT) ETCHED SIDE OF A PRINTED CIRCUIT BOARD

Of the numerous processes used in the fabrication of printed circuits, the most common were etching, plating, metalizing and printing.

In the photoetching process, a photosensitive film is applied to the copper surface of a copper-clad plastic sheet, and a photographic negative of the circuit pattern is superimposed on the sensitized film. The film is then exposed to ultraviolet light in a manner similar to that used in producing a photographic positive. The exposed film hardens and the unexposed areas dissolve readily in an alcohol solution. The hardened film protects the printed circuit pattern during the subsequent etching process. The exposed copper is dissolved in an acid or ferric chloride etchant bath, leaving the copper circuit pattern.

In stencil etching, a protective film to form the circuit pattern is applied by a printing process such as silk screening, which deposits a film sufficiently thick to protect the copper from the etchant solution. The protective film, an enamel, is dried and the exposed copper is etched as described previously.

In the plating process a plastic laminate is first coated with a material which will conduct electricity. This may be done by forming a .0001-in. silver coating on the surface of the laminate in much the same way that mirrors are silvered. The silver film is then coated with a plating resist, usually an enamel, by a stencil printing process, leaving exposed areas to form the circuit pattern. The plating process is similar to the plating of decorative metals. After a sufficient thickness (0.001 in. to 0.005 in.) of copper is deposited

the plating resist is removed by a solvent. The exposed silver film is removed by acid etching, leaving the much thicker copper plating to form the circuit pattern on the plastic sheet. Another technique, especially for electronic components (switches, commutators and other low-current-carrying parts), is to evaporate metal such as silver directly on an insulating plate through a stencil.

The printing method of producing circuits uses ceramic or glass as a base material in most cases. A silver paste is applied through a silk screen to form the circuit pattern. After the silver paste has dried, the circuit is fired in a furnace at about 750° F., thus bonding the silver pattern to the base. This process also makes it possible to print resistance elements, composed of various forms of carbon, on the circuit pattern.

Printed circuits assumed an important role in industry because they opened the way to mechanized production of electronic equipment. Mechanized production in turn offered the advantages of lower labour costs and better uniformity and quality of product.

Printed circuitry also eliminated one major cause of unreliability in electronic equipment, poorly soldered joints between the electronic component and conductor, by permitting the use of the dip soldering process. In dip soldering, the joints between the electronic component and the conductor are exposed to molten solder and joined in one operation.

Printed circuits were used in practically all types of electronic equipment, including radio and television sets, guided missile controls, electronic computers and industrial control equipment.

BIBLIOGRAPHY.—*Printed Circuit Techniques*, National Bureau of Standards, Circular 468; *New Advances in Printed Circuits*, National Bureau of Standards, Miscellaneous Publication 192; *Proceedings of the Symposium on Printed Circuits*, sponsored by the Engineering Department of the Radio, Electronics, Television Manufacturers Association (Jan 1955). (L. K. L.; Co. B1.)

PRINTING is the mechanical multiplication of text, pictures or designs by putting ink on paper or some other suitably receptive surface. Broadly speaking, printing encompasses all production and use of printed matter. This article discusses first the history of printing and then the modern printing processes.

There are three main methods of printing: letterpress (or relief), in which the image is transferred from a printing surface raised slightly above the body of the type or printing plate; intaglio (engraving), from a design engraved below the surface of the printing plate; and offset lithography (planographic printing), from a flat surface. Letterpress, which was used by the first European printers in the 15th century, is still the commonest method and is described at length below. The other two methods are described more fully in **GRAVURE** and **LITHOGRAPHY**.

Modern printers use techniques and processes that are continually improved through science and engineering, although the basic machines and methods change slowly. Printers choose the printing process best suited for the work to be done, and frequently they use different methods interchangeably or in combination.

THE HISTORY OF PRINTING

The East.—Printing as western civilization knows it began about the middle of the 15th century in Germany. The Chinese, Japanese and Koreans used printing long before that time, but western printing was invented independently of the oriental art and developed along dissimilar lines. The major reason for the separate development is the difference between Asian and European scripts. Mass production of movable letters for the 15th-century European alphabet of 23 letters was a simple affair; for a language demanding thousands of complicated ideographs, it was impossible.

Chinese printing was until modern times achieved mainly from wood blocks engraved in relief, each with one or more pages of text printed not under pressure but by rubbing the paper against the inked surface with a dry brush or some other rubbing device. As both sides of the thin, porous Chinese sheet cannot be printed, the traditional Chinese accordion book is folded and stitched at the side so blanks do not show. Skilled Chinese craftsmen not only could engrave the blocks rapidly and cheaply but also could duplicate with remarkable fidelity the beauty and delicacy of brush calligraphy, esteemed for aesthetic as well as utilitarian reasons.

How or when printing was first accomplished in China is not

known with certainty. It may have derived from engraved seals, used in China from at least the 3rd century B.C. to make impressions in soft clay. The first-known inked impressions on paper date from the 5th century A.D. Similar stamps, used with a red ink made from cinnabar, are still commonly employed in the east for signatures on documents. In the 6th century A.D. large wooden seals were cut and used for printing Taoist charms.

Another hypothesis is that printing developed from the ancient Chinese practice of making inked rubbings or squeezes from stone inscriptions. About A.D. 165 the standard text of the Confucian classics was cut upon stone to ensure permanence and accurate transmission, and soon thereafter the practice of making copies by means of ink rubbings began. The earliest extant rubbing dates from the 7th century. In the east and later in the west the first great patrons of the printer were officials of church and state, who saw in him a useful ally for maintaining canonical purity of Scripture and law. They recognized the value of printing's ability to transmit an almost exact facsimile, so that once an accurate text was established it was possible to minimize the corruption caused by accretion of scribal errors.

The oldest-known true printed piece, dating from A.D. 768–770, comes from Japan, where Buddhist missionaries had introduced printing from China during the previous century. It is a Buddhist charm, printed by order of the empress Shōtoku, from wood blocks or thin cast-metal plates, in an edition of 1,000,000 copies. Numerous examples have survived. The oldest printed book in existence also is of Buddhist origin. It is an edition of the *Diamond Sutra* consisting of six sheets of text and one smaller leaf with a woodcut illustration, printed in A.D. 868. The sole known copy, found in a cave in Turkistan in 1900 and acquired by Sir Aurel Stein in 1907, is now in the British museum. Religious texts, however, did not constitute the whole of eastern printing. Textiles, playing cards and paper money also were printed from blocks.

The Chinese attempted to use typography, as distinguished from block printing, despite the difficulties of trying to cast, compose and redistribute the thousands of characters required. The first trials are attributed to one Pi Sheng, who made individual characters of thin, fired earthenware for assembly in an iron form. These proved too fragile to be practical. The Chinese later cast letters in tin and cut them from wood, but none of these methods gained wide popularity. A type foundry was established in Korea late in the 14th century, where numerous fonts of type were cast in bronze. Although the use of metal type spread back to China and Japan from Korea, it superseded the use of the wood block as the principal printing method only in the 20th century.

The West.—Although any attempt to describe the invention and spread of printing in Europe can be based on somewhat firmer premises than the development in the east, there are still many gaps in our knowledge. The year 1440 has traditionally (and arbitrarily) been chosen as the date of the invention, and Johann Gutenberg (q.v.) is credited with the feat. However, Gutenberg was but one of many seeking to speed book production through mechanization; others were carrying out similar experiments in the Netherlands, France, Germany, Italy and elsewhere. Gutenberg was the first to assemble the necessary components of the printing process—type production, ink manufacture, the press, paper supply—into a coherent whole. The 15th century was a propitious time for the work. There existed a great market for books among the students of the rapidly expanding universities and the many literate members of the rising middle class, for reading was no longer a clerical monopoly. There was a well-organized book trade to market the sudden explosion of production. Paper, introduced into Europe through Spain and Sicily in the 12th century, was abundant and no longer suspect as impermanent.

As in the far east, block printing was the predecessor of printing from movable type in Europe. By the early 15th century blocks were being used to print textiles, playing cards and religious pictures. Block books, which combined pictures with simple texts and were printed by rubbing from inked blocks, made an appearance in the west soon after the first typographic pieces.

Gutenberg possessed two skills essential for successful volume production of individual movable types: metallurgy and engraving.

He was able to develop an alloy of lead, tin and antimony that would cast easily and would be durable. More important, he could engrave single letters on the hardened steel punches used to strike matrices for the casting of type—a technique already in use for the manufacture of coins and medals. Gutenberg's major invention was the mold that could be adjusted to receive matrices of various width (both the letters *i* and *m*, for example, had to be accommodated). The other technical problems of printing could be solved by adaptation of existing materials: presses were commonly used to make wine, oil, paper, etc.; the inks used for writing or block printing could be stiffened to the proper consistency for typographic printing. The best of the incunabula (*q.v.*; books printed before A.D. 1501) attained a degree of beauty and technical excellence rarely equaled since.

What little is known about Gutenberg and his invention comes from legal records. Unable to finance his work, he had to borrow from a fellow townsman, Johann Fust (*q.v.*), who became impatient for a return on his investment and in 1455 foreclosed on the inventor. Before then Gutenberg apparently had produced a few small pieces and probably had begun work on the Bible known by his name. Fust employed Peter Schoeffer, later to become his son-in-law, to assist in the new enterprise. Their firm produced many notable books, among them the great Psalter of 1457, the first book to use more than one printed colour and the first to carry a colophon naming its printers and the date and place of publication. The types for these first books copied the hands written at the time, and consequently they contained a great number of ligatures and contractions that were gradually eliminated later, since economy demanded simplicity.

Printing spread with extraordinary rapidity. From Mainz it proceeded throughout Germany in the 1460s, chiefly along the Rhine, the principal trade route. By 1500 there were presses in more than 60 German towns. The first printers in most European countries were itinerant Germans who had been lured by the promise of patronage or forced to emigrate by the intensity of competition at home. The first Italian press was established at Subiaco, near Rome, in 1464; Basel, Switz., had a press in 1465; Paris and Utrecht, Neth., had printers in 1470, Spain and Hungary in 1473, England in 1476 and Sweden in 1483. All Europe except Russia, which had no press until 1563, had printers during the 15th century. By 1500 more than 1,700 presses in almost 300 towns had produced one or more books. It is estimated that almost 40,000 editions were published during the 15th century, comprising somewhere between 15,000,000 and 20,000,000 volumes. These were mainly liturgical, theological and legal works, but by 1500 many texts of the Greek and Latin classics had appeared, as well as literary works in the various vernaculars. William Caxton (*q.v.*), the first English printer, published almost every important work of literature written in his native language before his death in 1491.

From Germany the centre of the printing industry moved to Italy during the late 15th century, especially to Venice, then at the height of its political and commercial importance. There Nicolas Jenson (*q.v.*), a Frenchman, established his press in 1470 and printed some of the noblest early books. His types included a roman face, based upon Italian book hands, that was widely copied and is still used in modern adaptations. Among modern type designers inspired by it were William Morris and Bruce Rogers. The most influential Venetian printer was the scholar-publisher Aldus Manutius, whose output included the first printed editions of many of the Greek and Latin classics. His three chief roman type faces were cut for him by Francesco Griffo of Bologna, who in 1500 was responsible for the first italic type, based on Italian cursive writing. These types, in small sizes, made possible the most important innovation of Aldus—small books that were the prototype of modern pocket-sized editions. (See also MANUTIUS.)

Early in the 16th century Italy lost its printing supremacy to France as a result of political and economic upheaval. Lyons and Paris became the great printing centres. French books had at first a distinctly national character, being printed mostly in *bâtarde* and other French Gothic types and illustrated in local style. Then, like architecture and painting, they began to show a strong italianate influence. A series of elegantly designed and printed

volumes produced by Geoffroy Tory (*q.v.*), printer, engraver and philologist, employed various types, decorative initials and architectural borders borrowed from Italian sources. These were highly influential in changing the appearance of French books from the Gothic to the Renaissance style. France's greatest contribution was in type design. Early printers had generally cast their own type, but during the first half of the 16th century type manufacture became an independent trade, highly specialized and centralized in cities with a concentration of printers, notably Paris, Frankfurt and Leipzig. Among the most notable of the early type designers was Claude Garamond (*q.v.*), who established himself in Paris about 1530 and sold his punches and matrices throughout Europe. His roman, italic and Greek types, either in their pure form or as adapted by subsequent cutters, dominated type design until the late 18th century and are highly successful in the modern revivals. Robert Granjon (fl. 1560), who worked primarily in Lyons, was another important type cutter; his work included the earliest *caractères de civilité* (a typographic version of the French secretary hand then in use) and flowered ornaments (*flourons*), which could be combined into innumerable decorative designs.

The wars of religion provided setbacks to the progress of printing in France. Many Huguenot printers emigrated to Switzerland, England and the Low Countries. Censorship and rigid trade regulations impeded French printing until after 1789. The centre of printing activity moved to the Low Countries, especially to Amsterdam and Antwerp. In Antwerp the establishment of Christophe Plantin (*q.v.*) became one of the strongest in Europe, with its foundry, bindery and bookshop. The firm remained in the family's possession until 1876, when the city acquired the premises and established the Plantin-Moretus museum. A great 16th- and 17th-century printing establishment has been reconstructed in the museum, with cases of type, punches and matrices, and ancient presses.

The New World.—Printing began in Mexico City in the 1530s, and the first press in South America appeared in Lima, Peru, in 1584. In 1638 the first press north of Mexico City was set up at Cambridge, Mass., by Stephen Day (*q.v.*), assisted by his son Matthew. The first two products of this press, which came under the control of Harvard college, were the *Freeman's Oath* and *An Almanac for 1639, Calculated for New England* by Mr. William Pierce, Mariner, of which no copies are known. The *Bay Psalm Book* (*The Whole Book of Psalms, Faithfully Translated into English Metre*) of 1640 is the earliest extant colonial book. Another interesting volume is the Indian Bible, the first American printing of the Scriptures, translated by the missionary Rev. John Eliot into the Indian language. Samuel Green and Marmaduke Johnson printed it at Cambridge in 1663.

Printing spread with colonization. William Bradford (*q.v.*) started in Philadelphia, Pa., in 1685 and moved to New York in 1693. William Nuthead began printing in Jamestown, Va., in 1698, but was not permitted to continue and moved to Maryland in 1709. Thomas Short, who set up a press at New London in 1709, was the first Connecticut printer, and others established the trade in localities from New Hampshire to South Carolina. Isaiah Thomas, from New Hampshire to South Carolina, established the trade in localities from New Hampshire to South Carolina. Isaiah Thomas, himself a successful printer and the first historian of printing in America, noted that 50 printers were active in the 13 colonies in 1775. The stamp tax on newspapers and advertising was one of the main stimuli for the independence movement in the American colonies. Printing proved its political power for the first time in the world's history: the book had been the intellectual foundation of the Reformation; the newspaper and the pamphlet prepared America for the War of Independence.

The 18th Century.—The 18th century was the first in which England developed any strong national typographic style and produced any influential innovators. Two are especially noteworthy: William Caslon (*see CASLON*), a gun engraver turned type founder whose reworkings of Dutch type faces dominated British and American printing for at least a century and still are widely used; and John Baskerville (*q.v.*), a Birmingham writing master who used a fortune made as a japanner to finance his unprofitable efforts as a printer and publisher. In his first book, the 1757 *Travels*, Baskerville used wove paper, the first printer to do so. His sharp

thin types, demonstrating his mastery of calligraphy and letter cutting, were a transition to the "modern" types of the early 19th century; and his severe, unornamented pages anticipated the neoclassic style of the 19th century. His most important influence was on the continent, where Giambattista Bodoni (*q.v.*) of Parma and the Didots of Paris (*see* Diderot) admired his work.

The two most important printing developments of the 18th century, however, were not aesthetic but technical. The first of these was the invention of stereotyping—a method of making duplicate printing plates by casting hot metal in a matrix molded from the original type. William Ged, a Scottish goldsmith, invented a method of stereotyping in 1725; it was not commercially successful, mainly because of opposition from the type founders and compositors. The Didots in France and Charles, 3rd Earl Stanhope, in England improved upon the process, and it gained wide acceptance about 60 years later. The other notable 18th-century invention was lithography, the only major printing method whose development can be fully documented. Alois Senefelder of Munich discovered and introduced the process during 1796–98. Lithography, which depends upon the immiscibility of grease and water, is the basis of all modern methods of offset or planographic printing. (For a detailed account, *see* LITHOGRAPHY.)

The late 18th century saw the beginning of enormous changes in printing, for during the Industrial Revolution printing became one of the first industries to utilize automation. Various problems had to be solved before the partially mechanized handicraft could be transformed into a high-speed factory operation. The most serious of these was shortage of paper, caused by a scarcity of rags. Various 18th-century scientists, particularly the German J. C. Schaffer, proved that paper could be made from the pulp and fibres of many plants, shrubs and trees. Use of vegetable pulp made practical the development of a machine for making paper in an endless web. The next requirement was a speed-up of the printing process itself, and this was accomplished primarily through modernization of the printing press.

Development of Modern Presses.—The wooden hand press, still essentially the same machine used in the 15th century, was the point of departure in the development of high-speed presses. In this development there were two avenues of approach.

One group of inventors wanted to maintain the basic design of the hand press but to improve its power and therewith its speed, size and general efficiency. The first steps were to replace wood parts with metal and to design every part on the basis of theoretical mechanics. The first man to do so was Wilhelm Haas (1741–1800) of Basel in 1772. But the local guilds prevented exploitation of this press, and it took a quarter of a century for other inventors to develop workable iron hand presses. Étienne Anisson-Dupéron in France, Charles, 3rd Earl Stanhope, in England, George Clymer in the U.S. and many others did notable work in this field.

The other approach was to connect the vertical and horizontal motions of the press in such a manner that they would form a complete cycle. The first record of this idea exists in the notebooks of Leonardo da Vinci. More than two hundred years later Friedrich König, a German, independently conceived the idea. He built the first flat-bed cylinder press powered by steam for the *Times* (London). On Nov. 29, 1814, the *Times* proudly announced that the issue in the reader's hand, the first printed on the cylinder press, was the result of "the greatest improvement connected with printing since the discovery of the art itself." The press had a capacity of 1,100 impressions an hour, in contrast to the 300-per-hour capacity of the hand-inked press it replaced. In 1848 Augustus Applegath and Edward Cowper constructed for the *Times* a press capable of 8,000 impressions an hour, which was handled by men at eight stations on a platform above an upright cylinder of cast iron that carried the type. In 1866 in the Walter press (named for John Walter III, then publisher of the newspaper), the *Times* achieved the prototype of the modern newspaper press—a true rotary press that printed both sides of a continuous web of paper fed from a roll; the rate was 25,000 impressions an hour. In the United States, meanwhile, Richard Hoe (*q.v.*) also developed rotary presses for newspaper

work. Most of the changes in press construction since the 1860s have resulted from the demand of periodical publishers for faster, more economical production. (*See also* PRINTING PRESS.)

Typesetting.—Once the press had been mechanized printers faced the problem of the supply of type, type composition and distribution of the individual types after use. Application of a pump to the type mold, which speeded production considerably, was one of a number of advances in hand casting in the early 19th century. Complete mechanization of type founding began with the casting machine of William Church, patented in 1822, which was capable of forming 3,000 sorts (individual pieces of type) per hour.

After the evolution of a number of impractical typesetting machines, the work of many inventors, Ottmar Mergenthaler (*q.v.*) in 1884 patented his Linotype machine, which cast thin slugs of type metal with a printing surface on one edge. Each slug was one line of type, molded from a row of brass matrices assembled by a keyboard operator. After the lines of type were used in printing the metal was melted for re-use. Almost simultaneously (1885) Tolbert Lanston invented the Monotype process, which casts type in individual letters. Both these machines, requiring large numbers of matrices, were made feasible by L. B. Benton's invention of the mechanical punch cutter.

The Linotype, Monotype and other similar composing machines involve the casting of metal type with the printing image in relief. Tremendous growth in the use of lithography, which does not require a raised surface for printing and which is prepared for the press by photographic processes, has intensified in recent years the search for composition methods that avoid the use of metal type. A number of photocomposition machines have been developed to assemble and transfer letters directly onto a sensitized plate from film matrices. Many typesetting functions have also been accomplished through the use of electronic computers. (*See* further TYPESETTING.)

Illustrations.—Acceleration of text printing in the 19th century was accompanied by parallel changes in the printing of illustrations as photography was applied to the making of printing plates. J. N. Niepce produced the first photomechanical plate in 1822 when he etched a reproduction of an engraving of Cardinal d'Amboise upon a sensitized metal plate that was subsequently used for printing. Shortly before his death in 1833 Niepce became associated with L. J. M. Daguerre, who subsequently perfected the first practical method of photography. Many experimenters sought to make line engravings on metal by photographic means, and Firmin Gillot succeeded in 1850. William Henry Fox Talbot, the Englishman who in 1839 introduced the calotype, the forerunner of most modern photographic processes, invented photogravure in 1852; Karl Klič (Klietsch) invented rotogravure in 1890. Other important 19th-century inventors include James Clerk Maxwell and Louis Ducos du Hauron, who during the 1860s established the principle of colour separation with filters to pave the way for colour-separation engravings and colour-process printing, and George Meisenbach and Max Levy, who late in the century perfected the halftone screen, which makes possible printed reproductions of paintings and photographs possessing light and shade. (*See also* GRAVURE; PHOTOENGRAVING; PHOTOGRAPHY.) (J. M. W.)

MODERN PRINTING PROCESSES

In the U.S. the term "printing" (originally restricted to letterpress printing) is used more and more generically for all kinds of graphic reproduction. Letterpress, before the perfection of photoengraving, was excellently suited for the reproduction of reading matter but much less suited for reproducing pictures and illustrations. Lithography and gravure, on the other hand, were strong in picture printing but weak in reproduction of reading matter. Application of science and photography to all printing techniques wrought a radical change. Letterpress became capable of printing pictures; gravure, lithography and other picture-printing processes were adapted to reproduce typographic copy. The gap between all of them was narrowed, resulting in the concept that "everybody who is concerned with putting ink on paper be-

longs to the printing industry."

All printing processes combine four elements: the printing surface or printing-image carrier (e.g., type face, printing plate, gravure cylinder); the press; the ink; and the paper or other printing stock. Each printing process employs its own printing surface, press and ink. The stock, on the other hand, may or may not be specialized.

Letterpress, also called relief or typographic printing, is the only process in which metallic type can be used on the press. It is used in producing books, magazines, newspapers, catalogues, packaging and commercial printing of all kinds (e.g., letterheads and sales forms). (See *Letterpress Printing*, below.)

Lithography.—Lithography is also called offset, offset lithography, photolithography, photo-offset and planography. Lithographic plates are in the main made photographically. Metal type is used indirectly in the form of a print or proof that is photographed for platemaking; a handwritten manuscript or drawing can be photographed in the same way. In the platemaking process the facsimile reproduction can be made larger or smaller than the original. Lithography is widely used in commercial, book, magazine and newspaper printing. In many applications, such as reprinting a letterpress book after the type has become worn, it is feasible to convert to offset by photographing either the proofs from the original type or the pages from a first edition. Offset is particularly suitable for making full-colour reproductions of paintings and colour photographs. (See further *LITHOGRAPHY*.)

Dry Offset.—Dry offset, or letterset, combines to some extent both letterpress and photo-offset. (No lithographic principles are involved.) A plate similar to a lithographic plate, but two or three times as thick (0.030 to 0.036 in.), is etched in relief, just as in photoengraving, but to a shallower depth (0.015 in.). When this plate is clamped around the cylinder of an offset press, it prints directly on the blanket, which offsets the image onto paper. Dry offset eliminates the need for the dampening system used in the lithographic process, this being its major advantage.

Gravure.—Gravure is an intaglio printing process in which the printing image consists of small wells in the surface of the printing plate. Ink is carried in the wells, their depths controlling the amount of ink transferred to the paper. Photogravure includes both sheet-fed gravure printing (used mainly for short-run printing of high-quality work) and rotogravure, the high-speed, web-fed process used for mail-order catalogues, newspaper supplements, packaging materials and other long-run work. As in lithography, text matter is photographed from type proofs or from films prepared in photocomposition machines, and since both reading matter and illustrations are broken into a screened pattern, fine lines of letters may become weak or ragged. To overcome this a fine screen can be used. (See further *GRAVURE*.)

Silk Screen.—A fundamentally different kind of printing is silk screen printing (q.v.), also called screen printing. The printing-image carrier is a stencil applied tightly against silk or some other fine fabric stretched tautly on a frame. Although the screen process is the youngest of printing methods, it utilizes the oldest principle of graphic reproduction of words and designs. Silk screen printing is preferred when a heavy, opaque layer of ink (or paint) is to be applied to a poster, book cover or sheet of glass. Fine detail can be reproduced by photographic methods, and halftones of suitable pictures can also be printed.

Flexography.—Flexography, originally known as aniline printing, is a form of rotary letterpress printing in which flexible rubber plates and fluid inks are used, mainly for packaging materials. The process originated in Germany in the late 19th century, and at first aniline dyes in alcohol were employed instead of ink. After packaging engineers took the process to the United States in the 1920s, thin inks consisting of finely ground pigments in a vehicle of solvent and resin were developed. Extensive use of cellophane for packaging greatly increased its importance.

Other Processes.—Other printing processes include: collotype (q.v.), also called the photogelatin process, which is a planographic method of printing continuous-tone images without a screen pattern; steel-die or copper-plate engraving, an intaglio process that produces a raised impression on letterheads and

calling cards; and several forms of raised-letter printing ("imitation engraving") called thermography, virkotyping or process embossing. Using letterpress methods and a slow-drying ink, the printed image is immediately dusted with a resinous powder by hand or machine. When heated, the powder melts and fuses with the ink to produce a slightly raised effect similar to the engraved result, though usually shiny in appearance.

Xerography, sometimes classified under printing processes, is actually a duplicating method often used to prepare a paper-type plate for small offset presses. It is fundamentally electrical rather than chemical or mechanical in nature; through principles of photo-conductivity and electrostatics, xerography transfers the original image (which can be simply a typewritten sheet or a printed proof) to another sheet of paper, or to a paper plate for small offset presses, when a large number of copies are wanted. Fine powder, instead of ink, is electrically deposited on the paper and fused into the surface by heat. This and other duplicating processes related to printing are commonly used in offices. (See *OFFICE MACHINES AND APPLIANCES*.)

Colour Printing.—Colour printing can be produced by virtually all of the printing processes. Though each process has a special system of preparing the printing plate itself, the fundamentals of colour printing are the same for each. Except for the use of simple line colour, colour printing usually refers to "four-colour-process" printing, though more or fewer colours may be used, depending upon the quality of the reproduction or the result desired. First steps in all cases require separation negatives made photographically from the original coloured subject, photograph or painting. As inks used for each of the different plates in process printing are transparent tones of red, blue, yellow (and black for definition), filters are used so that each separation will represent a corresponding portion of the colour spectrum. One separation usually continuous tone, is made for each of the colours to be used in the printed reproduction. From each separation a screened positive is prepared for the printing plate, each separation having a different screen angle, so that the final halftone will give the illusion of many colours from the intermixed screen pattern. (See *PHOTOENGRAVING*.)

LETTERPRESS PRINTING

Graphic-arts terminology is neither precise nor fully descriptive. Originally the names of the printing processes were more or less exact, but in the course of history techniques changed and expanded while the terms remained the same. The term "letterpress" refers to movable types, as does typographic printing, but neither includes or implies the printing of illustrations. "Relief printing" is a much newer term that overcomes these semantic differences and indicates that only the raised surfaces of the printing-image carrier actually print. But relief printing as a generic term includes many special fields, such as newspaper printing and flexography, not normally included under the term "letterpress printing." As used here, letterpress printing means the general range of applications, such as commercial, book and magazine printing.

Typesetting.—Letterpress printing is based on the use of type for text and photoengravings for illustrations. Typesetting is done in several ways. Most reading matter for books, newspapers and magazines, as well as commercial printing type, is machine set, either on linecasting machines, like the Linotype and Monotype, which mold each line in one piece, or on the Mergenthaler typesetter, which produces lines made up of individual types for each letter, space and punctuation mark. Hand composition, whereby a skilled worker (called compositor) assembles individual foundry types (types purchased from a foundry), has not been entirely replaced by mechanical typesetting, but the function of the compositor has been changed to setting display type (headlines and arrangement of larger sizes of type) for advertising, title pages and similar typographic art. The composition of display type was technically advanced by the Ludlow system, which utilizes hand-set matrices in a special composing stick. After assembling and spacing the matrices, the compositor makes a hot-metal casting of the entire line. Many printers set their own type, but others buy type com-

position from specialized typesetting houses. (See also PRINTING TYPE; TYPESETTING.)

Photoengraving.—Photoengraving converts pictures and artistic decorations into a printable form. The process combines photography, etching and manual engraving in making pictorial relief printing plates known as cuts, blocks or engravings. Photoengraving copy may be photographs, paintings, wash drawings or other illustrations containing tonal values that must be reproduced by the halftone process, or it may be pen-and-ink, crayon or pencil-line drawings; a written signature to be reproduced in facsimile; or any similar material that can be rendered in "line cuts" with no tonal values. Such copy is photographed and its image (which may be smaller or larger than the original) transferred to a metal surface by means of photoprinting. After the image has been photoprinted on the metal, the nonprinting areas are removed by etching.

In the 1940s a German manufacturer introduced an automatic electronic halftone engraving machine that scans photographs and controls a stylus to cut, rather than etch, the pattern on the printing plate. This machine has been developed to make colour-printing plates from photographic transparencies and other colour copy.

Wraparound Plates.—Wraparound plates for rotary letterpress presses are large photoengravings covering the full printing area of the press. A thin flexible plate is wrapped around the plate cylinder in a manner similar to that used for an offset press. (See also PHOTOENGRAVING.)

Duplicate Printing Plates.—Type and relief engravings are used not only directly on the press as printing surfaces but also as originals in making duplicate printing-image carriers. Short press runs are mostly printed directly if machine-set type is used, but long runs require duplicate plates. Even for short runs in which some or all of the type is foundry type, duplicate plates are preferred in order to prevent wear of the relatively expensive foundry type, which generally is used only for making electrotypes or reproduction proofs. Rotary printing and other specialized branches of relief printing cannot use type or engravings but must have duplicate printing plates.

Duplicate plates (1) preserve photoengravings and foundry type; (2) are suitable for much longer runs than are type and photoengravings; (3) permit combining type and engravings into a single plate that replaces a locked form containing various elements; (4) can be curved for use in rotary printing; (5) make possible the printing of multiples (many units of the same subject) in one press run; and (6) permit simultaneous printing of a subject in several different places, an essential feature for national and international advertising.

The four most important kinds of letterpress duplicate plates are stereotypes, electrotypes, plastic plates and rubber plates. Each has its own applications: stereotypes, which are most important in newspaper printing, are also used in bookwork and trade-paper advertising; electrotypes are used for duplicating forms containing fine halftones and for most rotary colour work done on presses other than newspaper presses; plastic plates are used as printing surfaces in bookwork and as intermediaries in machine plates for magazine advertising; and rubber plates are used for continuous forms, corrugated containers and flexographic printing.

All letterpress duplicate plates require at least one intermediary step between the original (type or photoengravings, or both) and the final duplicate plate, for both the original and the duplicate are in relief, and it is impossible to make a relief plate from a relief plate without an intaglio intermediary, or mold. The intaglio mold is made by pressing some suitable material (either hot or cold) against the original. The duplicate plate formed from the intaglio mold then is a relief plate suitable for letterpress printing.

Three qualities are essential in duplicate printing plates: retention of original detail, dimensional stability (or accuracy) and correct printing height. Detail must not be lost during the several steps whereby a duplicate plate is made from an original plate, a requirement particularly important in halftone printing; dimensional

exactness is prerequisite for register (the correct position of all printing on the sheet), particularly in colour work; and printing height determines uniformity of printing quality of all plate areas.

Stereotypes.—Stereotypes for newspaper printing are made routinely in newspaper plants, especially in those using rotary presses where entire pages are cast in stereotypes for mounting on the press. They are formed by first making a mechanical imprint of the printing form (type and engravings) in a matrix, or mat, made of a material such as papier-mâché. The mechanical imprint is thus an intaglio mat, and the final product of stereotyping is obtained by casting hot metal in this mat. Stereotypes are suitable for printing type matter, line cuts (e.g., cartoons and trademarks) and coarse halftones.

Assembling the printing form is the first step in matmaking. Thereafter the mat is pressed by one of three methods to produce cold-rolled mats, cold direct-pressure molded mats or baked direct-pressure molded mats. While cold-rolled mats are made by rolling in a press, the other two kinds are made in a hydraulic press that applies pressure over the entire surface of the printing form at the same time. After pressing, the mat is separated from the form, trimmed and made ready for use as the mold for casting hot type metal. Newspaper stereotypes used on rotary presses are cast curved; but those used on flat-bed presses or as part of the printing form for a rotary mat are cast flat. Those for book and publication work usually are used on flat-bed presses and therefore are cast flat. Curved casting is done on equipment that casts, cools, shaves and delivers the completed curved stereotypes ready for the press. Although curved casting may be performed automatically, flat casting is much less mechanized. The mat is first backed up (i.e., filled in with pieces of stiff paper) in the nonprinting areas that would otherwise be flattened by the weight of the metal during casting. Then the mat is baked, or "scorched," to remove moisture that would turn into steam during casting and could by rapid expansion produce an explosion. After scorching, the mat is placed in a casting box and cast in a vertical position. Stereotypes are either made type-high or are shell cast for mounting on a base. They are subjected to various finishing operations and are nickel plated whenever long-wearing qualities are desired.

Electrotypes.—Electrotypes are duplicate printing-image carriers that can combine various kinds of type with photoengravings. They are suitable for long runs, retain the detail contained in the original printing-image carriers with high fidelity, are of excellent dimensional stability, can have premakeready (adjustment for the proper printing height) incorporated and are well suited for rotary printing. While stereotypes are the press plates used almost exclusively for newspaper printing, electrotypes are the plates used for the rotary letterpress printing of magazines, catalogues and a variety of other products. (See also ELECTROPLATING; ELECTROTYPING.)

Plastic Plates.—Plastic plates are used primarily to print books, multiple forms and newspaper advertisements. They can be made either directly from the original printing-image carrier or from an electrotype pattern plate. After the pattern plate is prepared, an intermediary intaglio mold is made with thermosetting material; this mold can be used for making more than one plastic relief plate. If the pattern plate is unnecessary because of the nature of the work, the thermosetting intaglio mold is made directly from the original printing-image carrier. The plastic relief printing plate is then made in the usual manner.

Rubber Plates.—Rubber printing plates offer many advantages. They can print on a wide variety of materials, can be curved and attached to the form cylinder easily and are suitable for long runs. Rubber plates are mainly used in flexography, though they are also used in letterpress printing; e.g., in the printing of forms, envelopes and books. They exhibit good printability except for halftone details.

Rubber plates are made from a thermosetting intaglio intermediary mold. The original printing-image carrier, which may be type, photoengravings or electrotypes, and the thermosetting molding sheet are preheated and then assembled in a hydraulic press that uses a maximum pressure of 400 pounds per square

inch for type matter and 1,000 p.s.i. for photoengravings or electrotypes. Approximately 15 min. are required for curing the thermosetting mold, with a platen temperature of about 300° F. (150° C.). After curing, the intaglio intermediary is separated from the relief original and is ready for use in molding the rubber relief plate. Various kinds of synthetic and natural rubber are used for making rubber plates. Molding takes place in 6 to 12 min. in a hydraulic press with a maximum of 1,000 p.s.i. and a platen temperature of 300° F. After molding, the rubber plate is stripped from the intaglio intermediary and mounted for printing.

Rubber plates can be mounted flat or curved by use of pressure-sensitive adhesives or double-coated adhesive tape. Rubber plates can be mounted directly on the impression cylinder or prepositioned on heavy paper or on a light metal sheet that in turn is mounted on the press cylinder.

Presswork.—During presswork the printing image is transferred to the stock, usually paper. Four elements must be coordinated in this operation: the press (called, except for proof presses, the printing machine in Great Britain), the printing-image carrier, the ink and the paper or other printing stock.

Printing presses perform four main functions: (1) they position the unprinted stock for receiving the impression; (2) they ink the printing-image carrier; (3) they make the impression by transferring the ink from the image carrier to the paper; and (4) they remove the printed paper. Four different units that correspond to these four functions can be distinguished on printing presses. They are: (1) the feeding unit; (2) the inking unit; (3) the printing unit; and (4) the delivery unit. In letterpress printing the ink is transferred directly to the paper in all cases but one. This exception is dry offset, in which the printing image is transferred to a rubber blanket and from there to the stock.

From the beginning of printing until the first quarter of the 19th century all four main operations—feeding, inking, printing and removing the printed sheet—were done by hand. During the 19th century these operations were slowly mechanized, and now modern printing presses perform all four operations automatically. Hand presses have become a rarity and are used only by private presses that print limited editions. (See also PRINTING PRESS.)

All letterpress printing requires many steps. Some are executed by the pressman (called the machine minder in Great Britain), some by his assistant and some in the shop's planning department.

Choice of Press.—The first decision is to select the right press for the job at hand. Though sometimes the choice of press is self evident, often detailed analysis and calculations are necessary. The time factor must also be considered, since the ideal press may not be available, and the job may therefore have to be put on another, less appropriate press.

Imposition.—The second decision concerns imposition, the layout for the printed sheet indicating the place of each page on both the front and back of the sheet. (Imposing is the act of executing this plan and must not be confused with making the imposition or deciding on its plan.) The styles of imposition differ mainly in the manner in which the front and back of the sheet are printed. The detail of the job as well as its finishing or binding have a great bearing on selecting the manner of imposition as well as arranging the detail within the selected style.

Preparation for the Press.—Once the imposition is decided, the printing-image carrier is prepared for the press. This operation aims not only at the proper positioning of all printing matter but also at its correct printing qualities, which depend on the correct height of the printing surface. (The standardized height of type is 0.9186 in.) Foundry type, Linotype slugs and Monotypes are all cast type-high and therefore merely need leveling. Photoengravings, made of 16-gauge metal (0.065 in.), must be mounted on blocks to become type-high and suitable for printing with type matter. Stereotypes are cast either type-high or 11-point (0.152 in.) high; electrotypes are all made 11-point high.

If only duplicate plates are used as printing-image carriers in flat-bed cylinder-press printing, the bed of the press is equipped with a metal plate base, often called patent base. The standard height of plate base is 0.759 in.; when to this is added the height of the electrotype, 0.152 in., the height becomes 0.911 in., leaving

0.0076 in. for makeready, which is described below. Some plate bases are honeycombed, others have a diagonal or rectangular pattern; all come in combination sections. The printing plates are beveled and attached to the base with hooks that grip the edge of the plate and are anchored in the base.

Lockup.—The locking up of forms consisting of type matter and blocked (mounted) photoengravings is done at the stone as the printer calls the stone- or metal-topped table used for imposing. The many elements constituting such a form are held in place by the chase, a rigid metal frame reinforced with movable cross-bars for large-size flat-bed presses. The printing matter is placed in the chase according to the imposition, and empty spaces are filled out with wooden or metal blocks called furniture. Expandable lockup devices known as quoins (pronounced "coins") are used to tighten the form. When the lockup man "imposes" a form, he is concerned with the alignment of its elements and with its height. All parts of the form are inspected and adjusted, if necessary, so that they are type-high. The imposed form is then placed on the bed of the press and made ready for printing.

Makeready.—In makeready the form is further leveled and prepared so that it can yield the best possible print. Three techniques are used: underlaying, which consists in placing paper in various thickness under the printing element; interlaying, whereby paper is placed either between the photoengraving and its mounting or between plate base and stereotypes or electrotypes; and overlaying, in which adjustment is made on the platen or impression cylinder in order to apply the right printing pressure on the various elements of the form. The last technique consists in taking an impression and building up the impression cylinder where more pressure is needed by gluing paper of different thicknesses at the corresponding places on the overlay sheet or by reducing its thickness where the pressure is too heavy. The overlay sheet is covered by the packing and tympan of the impression cylinder. Hand-cut overlays for improved halftone reproduction can be supplemented with "chalk" overlays as a faster and better procedure; more recently mechanical devices have been developed to produce halftone overlays for a full press sheet semiautomatically. Makeready, which requires great experience and can be time consuming for big forms, can be reduced by premakeready operations that help to prepare the form for proper printing before it is put on the press.

On the Press.—Once the press is running, the pressman and sometimes one or two assistants keep constant watch to maintain efficient production and the right quality. They check colour and register often and watch for work-ups or press batters (elements of the form that somehow become loosened). New paper must be put in feeding position and the printed sheets removed. Offsetting (unintentional transfer of wet ink from one sheet of paper to another) is controlled by using drying devices on the press, fast-drying inks, or "smut sheets" that are laid between the printed sheets.

PRINTING PRESS, the machine in which type and illustration images are transferred to paper by means of printing ink. Printing presses can be classified into two major groups—flat-bed and rotary—according to whether the form (spelled *forme* in Great Britain) used for printing has a flat or curved surface. Flat-bed presses can be further subdivided as platen or cylinder according to whether a platen (flat plate) or a cylinder is used for impressing the paper against the printing surface. Presses also can be classified in several other ways; e.g., according to the nature of the printing surface: (1) letterpress, in which the image is printed directly from type or other relief surfaces; (2) planographic (e.g., offset lithography), in which the image is printed from a chemically treated surface; (3) intaglio (e.g., gravure), in which the ink is transferred from wells etched or engraved in the printing surface; and (4) silk screen, in which ink is forced through a silk screen to print an image. Presses also can be described by various other features; e.g., according to whether the paper is fed into them in sheets or as a web from a roll; whether the sheets are fed by hand or by automatic devices; and whether one colour, two colours or more than two colours can be printed. In addition, flat-bed presses often are described by the number of revolutions made by the cylinder for each impression or according to whether the type bed is horizontal or vertical. Presses also are sometimes classified according to the size of the impression area or the number of pages, expressed in various standard sizes, that can be printed in one cycle, impression or cylinder revolution. Modern letterpress and offset machines also are classified as oil ink presses if no drying methods are used to set the ink and as heat-set ink presses if drying means are used. Heat-set presses usually print on both sides of a web of paper; this process is known as perfecting, or backing up. (See also PRINTING; PRINTING TYPE; LITHOGRAPHY; GRAVURE; SILK SCREEN PRINTING.)

Developments Before 1900.—Early Hand-Operated Presses.—There is no exact knowledge of the earliest presses although there is no doubt that Johann Gutenberg (c. 1398–c. 1468) must have used one. The earliest mention of a printing press is in the evidence given at a lawsuit against Gutenberg in Strasbourg in 1439 by Conrad Sahspach, a wood turner who had constructed a press for one of Gutenberg's partners.

A model for the first printing press was available in the heavy wooden presses used in the paper mills of that time; these presses operated on a principle that can be traced to the Roman wine and olive presses described by Pliny the Elder. They consisted of two stout upright pieces of wood joined by two horizontal beams. A screw, working in the upper beam and turned by a long bar, exerted pressure downward upon a wooden plank placed on the paper. Certain modifications had to be made to obtain a quick, precise impression from the type. The pitch of the screw was made

steeper than in the paper press so that the necessary rise and fall was gained within the quarter turn obtainable with a fixed bar. The twisting motion of the turning screw was counteracted by suspending the platen (the wooden plank) from a hollow wooden box (the hose) that slid inside closely fitting guides while the screw turned freely within. The upright beams were frequently braced to the ceiling to keep the press steady. To make the type more accessible for inking, it was drawn on rails from under the platen by a windlass. To the back of the "carriage" which bore the type, a frame tightly covered with parchment (and therefore called the tympan) was hinged. This frame bore the paper, which was attached to it by projecting points and by a light folding frame (the frisket).

Most of these features can be seen in the first-known representation of a printing office, a wood engraving of about 1499, and in the many illustrations of presses used as marks by printers during the 16th century. Many of them are very massive, with thick wooden screws. The introduction of a metal screw is credited to Leonhard Danner (d. 1585), a screw maker of Nürnberg; this innovation greatly reduced friction, making the press easier to operate.

In the first of all printers' manuals, *Mechanick Exercises* (1683), Joseph Moxon recommends an improved Dutch press devised by Willem Janszoon Blaeu. Its only improvement appears to have been the substitution of an iron framework for the hose; it may also have been provided with a brass or iron platen, which seems to have been a common feature of presses in Holland, France, Italy and Germany from the end of the 16th century.

Further improvements were attempted during the 18th century. Printers who prided themselves on "fine" printing, such as J. Baskerville, the Didot family and G. Bodoni, took particular care with the construction of their presses.

The radical defects of the wooden hand press were the lack of stability caused by loosening of the joints and the slowness of operation. The output of a hand press, worked by two pressmen, does not appear to have varied greatly and payment was generally calculated on a rate of 250 sheets an hour printed on one side. Newspapers might have been printed somewhat faster, but careful work required a much slower rate. The stability of hand presses was improved by the substitution of iron for timber. In 1772, Wilhelm Haas, a typesetter at Basel, completed a press with a framework of cast iron and with an iron platen that covered the whole form at once. Local difficulties prevented its development so that it did not gain the immediate recognition and praise accorded the iron press built to the designs of Charles, 3rd Earl Stanhope (1753–1816), by his engineer, Robert Walker. In this press a system of compound levers added to the power of the screw at the moment of impression.

Shortly after the beginning of the 19th century, many lighter and more powerful iron presses that dispensed with the screw were devised. The Columbian press, invented about 1813 by George Clymer of Philadelphia, used a system of compound levers and became popular in Great Britain, France and Germany. Most other iron hand presses incorporated a kind of knuckle joint. The pioneer among these was the press of John I. Wells of Hartford (Connecticut), patented in 1819, which was superseded by the Washington press of Samuel Rust of New York (1821). In Great Britain, the Albion press, devised about 1822 by R. W. Cope, shared, with Clymer's Columbian, the supreme position among iron hand presses throughout the rest of the 19th century. Its robustness and simplicity gave the iron hand press an almost unlimited working life.

The Cylinder Press and the Use of Power.—In 1790 William Nicholson of London patented a printing machine in which the sheet of paper passed between an impression cylinder and a cylindrical printing surface which was inked by a system of rollers. Although this machine was never built because of the difficulty of preparing a cylindrical printing surface, the most important advances of the next century were to be based on it.

The first power-driven printing machine was the work of Friedrich König, born at Eisleben in Saxony, who came to England in 1806. Encouraged by some of the London printers, he patented a

FIG. 1.—ENGRAVING BY ABRAHAM VON WERDT, 1640–80, SHOWING ANCIENT PRINTING SHOP WITH LIGHTLY CONSTRUCTED WOODEN PRESS

machine in 1810 that was, in effect, a steam-driven hand press with automatic inking rollers. The first of these machines was built at the expense of Thomas Bensley, for whom it printed sheet H of the *Annual Register* in 1811 at a speed of 800 copies an hour. König's subsequent experiments, with an impression cylinder in place of the flat platen, led to an order for two machines from the *Times* (London). These were first used to print the edition of Nov. 29, 1814, which proclaimed itself "the first newspaper printed by steam." They printed 1,100 sheets an hour on one side; the speed was later raised to 1,800. König also built a double cylinder machine that produced 750 sheets an hour printed on both sides. In 1817 he returned to Germany, where he set up his own printing machine works. Important improvements to his machines were made by Augustus Applegath and Edward Cowper, appointed engineers to the *Times* in 1818, who in 1827 supplied new machines capable of 4,000 to 5,000 impressions an hour. Among other early cylinder machines, the one built by David Napier in the early 1820s is notable for the introduction of grippers in the cylinder to hold the sheet of paper.

The mechanical advantage of the cylinder made it possible to print larger sheets, but the weight of the heavy type bed and the necessity for reversing directions as it moved rapidly backward and forward under the roller were severe limits on speed.

A machine following Nicholson's design, but with the type attached to the four sides of a revolving prism, was built by Brian Donkin (patented 1813), and in 1816 Cowper patented a means of forcibly curving stereotype plates, which could then be attached to a cylinder.

The Rotary Press.—The first rotary press employed a number of cylinders that rotated in contact with a central cylindrical printing surface. This obviated the need to move the flat beds of type. The first manufacturer to produce a successful rotary machine was Richard M. Hoe (*q.v.*) of New York, whose "type revolving machine" (patented 1845) was installed by the *Philadelphia Public Ledger* in 1847. The type was locked on a large central cylinder by means of wedge-shaped rules, and four impression cylinders were spaced around it, separated by four inking systems. Each

FIG. 2.—TEN-FEEDER "TYPE REVOLVING MACHINE" PATENTED 1845 BY RICHARD M. HOE

impression cylinder was individually fed, so that the 2,000 revolutions an hour of the central cylinder (whose printing surface was in fact polygonal) produced 8,000 sheets printed on one side. Applegath produced a machine incorporating the same principles for the *Times* (patented 1846, erected 1848), with the difference that the axes of the type cylinder and eight impression cylinders were vertical. The Hoe rotary, with an increased number of impression cylinders, was imported into England to print *Lloyd's Weekly Newspaper* and in 1858 was adopted for the *Times*.

Two further developments were required before the rotary machine could be used efficiently: a new method of casting stereotype plates, and a mechanical device for feeding the paper. Following Cowper's experiment with forcibly curving stereotype plates, several attempts were made to cast curved plates. The substitution of papier mâché for the earlier clay or plaster mold (a French patent of 1829) enabled Charles Craske to cast curved plates for

FIG. 3.—PRINCIPAL METHODS OF PRINTING

full benefits of the rotary principle were obtained. In the United States, the Hoe firm developed the multiple-unit press for the production of large newspapers.

Book and Job Presses.—The rapid pace of development in printing presses during the 19th century was mainly attributable to the demands of newspaper and periodical publishers, but press manufacturers also produced two important types of book-printing machines. In the stop-cylinder machine, the cylinder rotated in gear with the bed of type on its forward journey and remained stationary on the return of the bed. The best known of these was the Wharfedale, which was the outcome of the experiments of William Dawson and David Payne during the 1850s in the Yorkshire town of Otley. In the two-revolution machine, the cylinder turned continuously, making one complete revolution for each traverse of the bed. The impression was made on the bed's forward traverse and the cylinder was lifted clear for the backward traverse. At the same time the principle of the platen was not wholly abandoned; the Napier double-platen machine of 1830, in which two forms moved alternately beneath a central platen worked by a knuckle joint, was valued for the high quality of its output.

The machine that revolutionized job printing (the printing of small posters and handbills, cards and letterheads) was the treadle platen, produced in Boston (Mass.) by Stephen P. Ruggles in 1855. The vertical bed, holding the type, was hinged to the bottom of the platen, on which the paper was placed. This machine was developed by George Phineas Gordon, who used the same principles and the same source of power (a flywheel driven by a treadle) for his Franklin press of 1858; this press was widely known under the name of the inventor and, from that of its first English manufacturer, as the "Cropper." Gordon introduced more powerful machines, known as art platens, capable of printing wood engravings and halftone blocks. (Js. M.)

20th Century.—The 19th century saw a complete revolution in the mechanical principles of printing; before it was over the foundations of all modern techniques had been firmly established. By contrast, the improvements made in printing in the first six decades of the 20th century, in which so many major advances were made in almost all other branches of technology, were, in the main, relatively insignificant mechanical modifications. In 1900 the standard jobbing letterpress machines were the platen, the stop-cylinder and the two-revolution cylinder press; the rotary principle was employed on a large scale only in the web-fed newspaper field. The rotary offset was already in course of development, and both

the *New York Herald* in 1854, and in 1861 Hoe presses were adapted to take such plates. In the early 1860s paper was still being fed to rotary machines by hand in individual sheets, although papermaking machines had been producing it in continuous webs since the first years of the century. In 1835, Rowland Hill produced an experimental type-revolving machine using a web or reel of paper, but the first application to a large rotary machine was made by William Bullock of Philadelphia. His machine (1865) cut the web automatically before it entered the impression cylinders. The *Times's* engineers had been working on a rotary web press since 1862 and the result, their Walter press (named for J. Walter, then owner of the *Times*), was put into operation in 1866. When automatic folding devices were added to these rotary machines and a printing cylinder was added for each impression cylinder, the

sheet-fed and web-fed rotary gravure presses were in operation. By 1950 the general situation had altered to the extent that offset lithography had usurped an important part of the letterpress field, but machines were scarcely more advanced technically: letterpress printing was carried out on flat-bed machines very similar to those in operation at the beginning of the century, and, indeed, many presses 50 to 60 years old were still operating and competing successfully with newer machines. Offset lithography presses were substantially identical in design to the first operational models introduced about 1905; and gravure printing had advanced little either in machine construction or in methods for preparing the printing surface. The only major printing process to have developed in the 20th century from the stage of an individual (and very ancient) art to that of a technology was screen printing.

Flat-bed Letterpress Machines.—In the early 1960s the letterpress machine was still, mechanically, the least refined of all printing presses. The flat-bed principle on which the majority of letterpress machines operates is extremely inefficient since it involves reciprocation, either of the type bed or, in the case of some platen presses, of both platen and bed. The reversal of direction creates two problems, one mechanical and one economic: first, considerable energy of momentum must be absorbed rapidly at the end of each movement without causing excessive vibration or heat; second, because the machine does not print on the return stroke, half of the total running time (on most presses) is unproductive.

In cylinder machines efforts have been directed to designing reciprocation systems in which the stopping and reversing part of the movement is speeded up so that it represents only a fraction of the complete printing cycle; as the form on the bed is not under impression during the return stroke it is possible to introduce special gear segments that take over the drive for this part of the cycle only. A letterpress cylinder machine known as the Printopress and introduced in Ireland in 1960 worked on an entirely different principle, developed from one of the many ideas born but then abandoned during the 19th century. In this press the bed remains stationary while a train of impression cylinders and an inking system moves around it on a planetary track.

Modern platen presses are available in a variety of ranges of size and speed; they are usually especially suited for a particular type of printing job. Most platen presses are used in small print shops for printing letterheads, handbills and similar matter. Their maximum printing areas range from about 7 × 11 in. to 14½ × 22 in. and their speed ranges from about 2,000 to 5,000 impressions per hour. Most platens are operated by electric motors, are fed sheets automatically and print one colour at a time. Web-fed platens that print up to 6,000 impressions per hour have been developed.

Most modern cylinder presses are designed to print sheets; their printing areas range from about 8½ × 11 in. to 45 × 68½ in. Hand-fed cylinder presses produce about 2,500 impressions per hour; those with automatic feeding devices can produce up to about

BY COURTESY OF R. R. DONNELLEY AND SONS COMPANY

FIG. 6.—MODERN ROTARY PRESS

6,500 impressions per hour. Cylinder presses, either sheet- or web-fed, are used to print books, magazines and other matter when good quality of reproduction is desired and when the required quantities call for press runs of up to medium length. These presses are also constructed to print two colours and to print both sides of the sheet.

Offset Lithography.—Possibly the most important single contribution of the 19th century to printing-press technology was the development of offset lithography (see LITHOGRAPHY: History). The great advantage of offset lithography over flat-bed letterpress is the rotary principle. In offset, the printing cylinder (the blanket cylinder carrying the image offset from the plate) runs continuously in one direction while the paper is impressed against it by an impression cylinder. There is no reciprocation, no change of speed, and the fundamental mode of operation remains the same whether the machine is sheet- or web-fed. In addition, offset plates, since they are thin sheets of metal, can be wrapped around the plate cylinder with ease. There is no need to cast or bend thick plates.

Offset presses are built in sizes ranging from that of the smallest platen to that of a medium-size rotary letterpress machine. For web-fed newspaper work, they have a maximum capacity of about 64 standard (or 128 tabloid) pages. These presses are built, as are letterpress rotary units, in four- or eight-page sections that can be arranged to suit the user. Such presses can be equipped for printing two or more colours. The top speed of a modern offset newspaper press is about 30,000 64-page (standard size) copies per hour. Sheet-fed offset presses can be equipped to print up to six colours in one run on one side of the sheet.

Rotary Letterpress.—Many difficulties are involved in printing letterpress by rotary means. The most common example of a rotary letterpress machine is the newspaper press, which has a number of inherent disadvantages: the curved or tubular printing plates, cast in stereo metal, require skill, experience and expensive equipment to produce and may crack under stress; the weight of the heavy plates (which can lead to damaging vibration in the axles of the plate cylinders) and unavoidable inaccuracies in their thickness make it necessary to print on a soft stock and against a soft rubber blanket if high press speeds are to be attained. This

FIG. 5.—MODERN WEB-FED OFFSET LITHOGRAPHIC PRESS

means that the quality of printing, particularly that of halftones, is not high.

Many nonmetallic materials have been investigated for molding letterpress plates in an attempt to find a surface combining sharpness with sufficient elasticity to give good halftone reproduction: these include rubber, Bakelite, polyvinyl chloride (PVC) and nylon. Apart from molding, letterpress relief plates can also be produced by embossing or etching. A small German press, the Printo, intended for use in offices, makes use of the embossing principle. A thin alloy sheet is placed in a standard typewriter, without ribbon, and the matter to be printed is typed onto it, giving a raised reversed image on the underside of the metal. The sheet can then be wrapped around the cylinder of the press and inked as a normal relief letterpress surface.

During the 1950s, following the introduction of new techniques for etching letterpress plates, there was a growing interest in the development of etched plates that could be wrapped around the cylinder of a rotary press and in the modifications necessary for this type of press. Within ten years, more than a dozen different models were in production, covering a wide range of sizes. A press using an etched metal plate differs from one using cast stereotypes in that the increased accuracy of the plate thickness makes great pressure between the impression cylinder and the plate unnecessary, only a "kiss" impression being required. For this reason modified offset machines were found eminently satisfactory in experiments. Modern production models of rotary letterpress machines closely resemble their offset lithography counterparts—indeed, machines adaptable to either process are available. Offset letterpress is also used in a number of applications, mostly of a specialized nature.

Modern sheet-fed rotary letterpress machines are used mainly for producing catalogues, magazines and similar long-run matter. Sheets ranging from about 21 × 15 in. to 52 × 76 in. can be handled, depending on the press. The number of impressions per hour ranges between 3,000 and 6,500. Up to six colours can be printed in one run. For long runs such machines usually can be adapted to print from a roll.

Modern rotary letterpress machines used in newspaper production are fed by web and are made up of basic 4- or 8-page units arranged to suit special needs. The speed of the newspaper press is limited by several factors; e.g., the resistance of the paper web to breaking, the rate at which the paper absorbs ink, and the speed of the mechanisms that collect and fold the printed paper. The units of the press can be arranged in a straight line on one level or can be stacked in several decks. The total capacity of a press varies according to the size of the paper; for example, in the U.S. the capacity of dailies with 10,000 or less circulation averages about 16 pages, those with 10,000 to 50,000 circulation usually have a capacity of between 24 and 48 pages and those with more than 50,000 circulation may be able to print as many as 128 pages in a run. Extra pages can be inserted into an issue by hand or with special folding machines. Web-fed rotary letterpress newspaper machines can print up to about 60,000 copies of 128 standard-size pages per hour; in the interest of reproduction quality and wear and tear on the press, however, newspaper presses usually are operated at about only three-fourths of their rated top speed. Large daily newspapers may operate as many as ten 128-page press units at one time in order to produce an edition quickly.

Advances in the Printing of Sheets.—Since 1900 the bulk of development in sheet-fed presses, whether printing by letterpress, planographic or intaglio process, has comprised a series of minor mechanical modifications designed to improve the speed of the machines. Stops in sheet-fed presses have been designed that do not cause the sheet to bounce back as it is being fed to the cylinder, and complex mechanical feeders have been devised to work at very high speeds. Swinging grippers take the sheet and accelerate it to the peripheral speed of the cylinder; after the sheet is printed it is taken by other grippers on a continuous chain and delivered printed side up onto a pile; special airblow devices can be employed to slow up the sheet as it is released. To prevent the transfer of wet ink from one printed sheet to the next, a powder or liquid is sprayed on each sheet as it is delivered or the sheet is

passed quickly over a small flame to speed drying.

Advances in Web Printing.—In the early 1930s the need for printing mass-circulation magazines at high speed became urgent. To increase the speed of printing on web with the rotary letterpress, methods for drying the printed image to set the ink were introduced. Better plates and paper quickly followed. By 1950 the web-fed rotary letterpress became an immense machine; some models weighed up to 200 tons and produced four- and five-colour folded signatures on smooth, coated paper at the rate of 20,000 per hour. Automatic paper reels also were introduced; these allowed new rolls of paper to be spliced to old ones without slowing the press.

Advances in Rotogravure.—Until the 1950s, rotogravure in the U.S. was used primarily to print newspaper supplements. The quality of this work was generally unsatisfactory because of poor colour register and variations in ink and colour. The introduction of photoelectric means of controlling colour register and of instrumentation for controlling ink density made high-quality rotogravure work possible by the late 1950s. After that time, complex 10- and 12-unit multicolour rotogravure presses with automatic paper reels were used to print magazines and catalogues at speeds up to 25,000 revolutions per hour. (B. I.)

PRINTING TYPE. This article discusses the design and designing of printing type from its earliest times down to the present. Related material will be found in **TYPESETTING**; **TYPOGRAPHY**; **PRINTING**; **PRINTING PRESS**.

The Beginnings.—The invention in Europe of printing with movable metal types in the middle of the 15th century introduced the principle of mechanical mass production to a world in which nearly all man-made objects were made one at a time by hand. The earliest designers of printing types were the goldsmiths and other skilled metal workers whose experience with coinage and medal cutting for replica casting enabled them to attack the far more complex task of carving and filing in steel the sets of male dies called *patrones*, or punches; i.e., model letters to be reproduced in quantity as characters on the faces (flat printing surfaces) of a font of type. The cutting of letters on so minute a scale, with strict consistency in the treatment of straight lines and curves throughout an entire alphabet, demanded a degree of manual skill which seems all the more spectacular in contrast with modern methods of cutting punches pantographically by power-driven tools from large mechanical drawings. But in admiring the virtuosity of the early punch cutters it is too easy to overlook their greater role in history; i.e., that of the first prototyping industrial designers. What they were making by hand was only a means toward what they were actually designing for batch production, namely the appearance of printed words on paper, specifically the ink prints of type in some particular size and style of a face (design) which would indicate, to a predicted class or group of readers, the general nature and purpose of the book at hand.

The pioneer punch cutter, like any other designer for industry had to take into account successive mechanical processes which might affect the appearance of the multiple end product. Thus the different letters of the alphabet had not only to be consistent in the treatment of stems, curves and serifs (fig. 2) but also had to

kjki

FIG. 1.—ALTERATION OF LETTERS IN SAME BODY SIZE BY CHANGING LETTER WIDTHS AND LENGTHS OF ASCENDERS AND DESCENDERS

appear on the printed page in accurate alignment, a matter which would partly depend upon the successful processing of the brass matrices (female dies) that were to be struck from the punches.

FIG. 2.—TYPE SAMPLES SHOWING DIFFERENT TREATMENTS OF THICKS, THINS AND SERIFS (TERMINAL STROKES)

into damped sheets of handmade paper and the resulting "squash" of viscous ink would leave the printed images of the characters looking considerably thicker and somewhat less sharp in detail than their steel prototypes. The modern type designer faces similar problems, made more complex by the variety of paper surfaces and reproduction processes in use today.

Above all, the early punch cutter knew that the printed pages would come as bound books into the hands of readers who were accustomed not simply to deciphering the code symbols of the roman alphabet as such but to distinguishing between different kinds of books at first glance by their conventional styles of lettering. What links the modern type draftsman to the Renaissance punch cutter, and labels them both as type designers, is the need to look ahead through a long chain of production stages toward the ultimate object of all typographic design—the conveyance to the reader of meaningful texts through letter images which that reader will accept as appropriate to that particular kind of printed matter.

Printing created its own, entirely new kinds of "matter" (notably the periodical), which in turn had to be envisaged by the type designer as functional problems in legibility. From the early 19th century onward, competitive advertising opened up the distinct need of "display" type design ("jobbing") in which the ruling intention is the very opposite of that which disciplines the designer of type for continuous reading. Letters for a handbill may legitimately imitate any fantasy or distortion of sign writing, for the aim is to arrest and focus attention on a few words. The bold type which appears in various modern works of reference (such as dictionaries and timetables) has the similar purpose of attracting the searching eye quickly to the relevant entry by its abnormal thickness. Type for continuous reading has the contrary aim; it must carry the reader forward through line after line by its self-effacing conformity to whatever norm of legibility the reader counts upon for that particular kind of text. Thus the deliberate exploitation of abnormality in type design is a relatively new development and the inventors of eye-catching advertising types, represented by thousands of different designs since the beginning of the 19th century, seem far closer to sign writers than to the metal cutters of the days when books and booklets constituted almost the whole output of the printing press. Even in the earliest years the designers of type were accepting the principle, already fixed by the medieval scribes, that different sorts of book—liturgical, legal, revived-classical, popular-vernacular—should have different styles of letter.

Fortunately for Johann Gutenberg (*q.v.*) and the goldsmith whose services he used while he was at work on his invention, the northern scribes had evolved a formal script for use in short double-column lines, in which high legibility-for-size was gained by the use of a broad stiff pen that gave maximum thickness to the down strokes. To achieve this blackness with least waste of space, the letters were condensed by being broken into angles and straight segments. The resulting *textura* script offered the metal engraver a model peculiarly suited to his file and burin. The readers of a bible in double column expected it to be set forth in this strong angular style of letter; hence the 42-line Bible (Mainz, 1456) gave them no jar of novelty (fig. 3). The round gothic associated with theological and legal texts in Latin, then the international language of the professional literates of Europe, was also

relatively easy to reproduce in metal. It too had been evolved

Quod cū audisset dauid: descendit in

FIG. 3.—LINE OF TYPE FROM 42-LINE BIBLE, ISSUED AT MAINZ; 1456. ACTUAL SIZE

for use mainly in narrow columns, where the amount of white space between the lines can safely be reduced by shortening the descenders and ascenders and thus increasing the apparent size of the letters. The stubby descenders of the prevailing black letter styles were well adapted to the type cutters' need to strike matrices by hammering the hardened letter punch into a slab of brass. The more informal and free-swinging *bastarda* style, mainly used for books in the mother tongue, again required little more than simple imitation (fig. 4).

But among a thousand these the one to

But as printing spread from Germany to the Italian cities, the pioneer punch cutters faced their first insuperable problem: that of reproducing in separate metal letters, and eventually in type prints, the delicate, open-curved, long-descender style of calligraphy with which the humanist scholars and their scribes were optically distinguishing texts in the Latin of classical antiquity—or their own sedulously "Ciceronian" Latin—from those in the modernized Latin of the schoolmen and lawyers. To the humanists, the "language of divine antiquity" was not only to be studied and imitated, it had even to be equipped with its own style of script in which subtlety and elegance, lightness and amplitude would replace the bold simplicities of the styles which were given the contemptuous sobriquet of "gothic." The script revived by the humanists for this purpose was the minuscule standardized by Alcuin under Charlemagne at the beginning of the 9th century. The type cutters never succeeded in producing a plausible imitation of it in metal; but as crude attempts at copying gave way to deliberate paraphrase in terms of metal casting, what emerged was the first new contribution of type design as a creative art; i.e., the kind of letter which is now called roman, or in French *romain*. Today the word is used broadly for "ordinary print" as distinct from anything exotic or attention-catching. But in Germany, where black letter survived as a language-linked style (*Fraktur*, *Schwabacher*), roman still bears its historical name of *Antiqua*.

Nicolas Jenson, formerly master of the royal mint at Tours,

Quare multarum quoq; gentium patrem diu

lower case and its inscriptional style capitals on the rising tide of humanist scholarship by perfecting a type which became the model for the great French type cutters of the next generation,

notably Claude Garamond, and so the direct ancestor of a long line of roman fonts, many of which have been revived for present-day use.

Aldus' roman of 1495 appeared in a literary exercise by Pietro Bembo, the humanist poet, later cardinal, who probably took a personal interest in its typography: successive copies show many variants made while the work was on the press.

Aldus' "pocket editions," dating from 1501, made the first use of the kind of type now known as italic; it originated with him as an imitation of the cursive minuscule in chancery style in which scholars had been swiftly copying out coveted texts. Italic was later equipped with its own sloped-roman capitals and adopted as an auxiliary to roman by being cast in alignment with it.

The subsequent history of roman type design falls into four distinct periods. Through the 16th and 17th centuries its treatment by successive engravers varied only in subtle detail, scarcely perceptible to the layman's reading eye, and its debt to the calligrapher remained evident in the angle of thickening or "stress" of the curves and serifs of the lower case. Type founders began, however, to offer alternative fonts of the same body size: one series (of sizes from small to large) for normal bookwork, with the longer descenders that help to create a channel of white space between the lines, and a larger-looking version with short descenders and condensed curves, suitable for narrow columns such as those of the periodical.

Transition and Revival.—The first effort to rethink and rationalize type design came in 1692–93 when Louis XIV commissioned his academicians to devise, and Philippe Grandjean to pro-

e, 25 d'Aoust, le Gouverneur se rendit à l'

duce; a new series of roman and italic for the royal printing office. Type cutting entered its "transitional" phase in which sharp thick-thin contrasts brought a new look to the page. In Paris in the middle of the 18th century the learned printer-type founder P. S. Fournier developed the new style in one direction, with ingenious decorative use of *fleurons*, or border units, cast as type. At the same time John Baskerville in Birmingham, Eng., commissioned a rounder and still more sharply cut roman and italic, one which showed off the elegance of his hot-pressed paper and improved ink. Baskerville's chaste neoclassic style had a profound influence on European type cutters.

The transition was in effect from "this style" to "this style," used by G. Bodoni and introduced in France by the Didots shortly before the French Revolution. Here the graver declared its independence from the quill, italic forgot its current script ancestry and the abandonment of the "long s" (ſ) drew the only dividing line in the whole history of roman type that is immediately obvious to the uninstructed reader.

The new short-s style with strong vertical stress and hair-thin horizontals became the prevailing mode for books and periodicals for the first half of the 19th century and the long-s fonts were melted down as antiquities. But just as the humanists had turned from the rigidities of gothic to their "antique" roman, so the Romantic movement in England brought a new appreciation of the "old" (pre-Baskerville) type cut by William Caslon, the first meritorious English punch cutter and letter founder, in 1720. A font preserved by the Caslon type foundry as a museum piece was used as a pastiche type at the Chiswick press from 1840. It found favour among antiquarians and liturgical publishers. In France, the "old" types of the 17th-century Elzevir editions became the inspiration of tentative revivals. The Scottish type foundry of Miller and Richard, sensing a change of taste, brought out in 1860 their historic (to contemporary taste) modification in which for the first time the "old" style reappeared, without its long s, as an alternative to the "modern."

Present Era.—This opened the present era in type design, with the new notion of offering publishers or customers a choice of different styles of roman. At first it meant a costly duplication of

the printer's type storage facilities; but the coming of the hot-metal composing machine reduced the problem to that of a simple change from one set of matrices to another. The term modern lost its meaning of "ruling mode of today" and became trade jargon for the sharper-cut style: "old style" and "old face" lost their antiquarian reference and took on a purely morphological meaning.

A present-day printer's type specimen book may offer an even wider variety of "composition faces" (for continuous reading) than is shown below (fig. 8). These examples, all of type faces in commercial use, are selected to indicate the different historical periods from which designs have been revived (with or without intelligent modifications) to meet the modern publisher's need for variety in taste and also for technical and economic reasons. Type (C), for example, is particularly suitable for printing on coated paper, which requires a very light impression; (E) is broad, (D) relatively condensed, and the difference can either save or bulk out 25 pages in a 248-page novel. (M) is effective in the long line of a book, where the space allowed for its deep descenders leaves a useful channel between the lines, but it is inefficient in narrow columns.

From 1885, Linn B. Benton's punch-cutting machine began to replace the hand craftsmen. New faces could thenceforth be drawn to any scale and cut with microscopic accuracy, in any type size from the same master pattern. The invention had little or no direct, immediate effect upon type design, for 19th-century punch cutters were not employed as creative designers; their pride was in their own manual skill, and there the machine surpassed them. The influence of the Benton machine was first shown in the emergence of the family of different versions (bold, condensed, etc.) of the same basic design—variants easily contrived by alterations to 10-in. drawings. Cheltenham, a roman designed by the U.S. architect B. G. Goodhue in 1905, failed as a book face but became the first runaway success in commercial printing as a family of many variant weights and widths. But meanwhile Benton's invention had made possible the composing machine; this major innovation was indirectly responsible for the emergence of a new class of types—the first bridge ever thrown between the quiet world of "book" faces (for continuous reading) and the restless, occasionally raucous and hitherto completely separate world in which the small jobbing printer's compositor had been confecting auction, theatrical and other "bills," trade cards, etc., from an ever-growing range of poster-like or otherwise attention-catching jobbing types.

Those faces, called in French *lettres de fantaisie*, had throughout the 19th century provided a not unprofitable sideline for the type founders, whose main income depended on the book and periodicals printers' demand for ordinary text type in the tonnages required for hand composition. Since no one took advertising seriously to begin with, no self-consciousness inhibited the inventiveness of its type designers and their licence to impudence was exploited with honesty and gusto. Delicate pseudocalligraphic script types had appeared for commercial and society printing before the Industrial Revolution, but now "shock" types offered a new field. Capitals without serifs or thick-thin stress (sans-serif) multiplied before 1825; fat black "Egyptians" (slab-serif) multiplied. The lithographic lettering artist's free fancies (e.g., on music title pages) prompted the punch cutters to new feats of skill. Much of the most self-conscious avant-garde typography of the 20th century has drawn upon the early Victorian job printer's repertory; the crude sans-serif called "grotesque" ("grot") has been most often resuscitated for modern experimentalist display.

The new composing machines swept away the type founders' main market and left jobbing types as almost their sole remaining stock in trade. American type founders, banding together under the threat of extinction, began to give serious aesthetic attention to advertising faces. Under the new and respectable name of "publicity types," classic faces of the past were revived primarily for use in brochures and displayed press advertising, which the newly arriving advertising agencies were treating with a solemnity unknown to the old handbill printer. Thus book and display faces drew at least within sight of each other. Today, a fine book

face is normally cut in sizes up to an inch high, where abnormality of size is alone enough to make it attention-catching; contrariwise, grotesques and sans-serifs have been used in small reading sizes by designers anxious to devise a "contemporary" style—for reasons more sentimental than rational, since no amount of respect for the machine age will reconcile book readers to alphabets which make it hard to distinguish I and l, or a from o.

FIG 8—MODERN REVIVALS OF EARLY TYPE FACES AND 20TH-CENTURY DESIGNS

(A) Cantar by B. Rogers, 1914, patterned after M. Jensen's roman, 1470; (B) roman by Aldus Manutius, 1495, prototype old face revived by Monotype Corp. Ltd., 1929; (C) roman by Aldus, 1499, recut in facsimile as Monotype Poliphilus, 1923; (D) roman by P. S. Fournier, revised as Monotype Fournier, 1925; (E) revival of roman by J. Baskerville, 1757; (F) roman by J. Bell, 1788, revived as Monotype Bell, 1930; (G) roman, revived from G. Bodoni, early 19th century; (H) Scotch Roman, 19th-century "modern" face; (I-L) four Italic faces showing development of modern style; (M) Perpetua, E. Gill, 1929; (N) Times New Roman, S. Morison, 1931; (O) Gill Sans, E. Gill, 1928; (P) Palace Script, oop-erlate jobbing face; (Q) Egyptian, slab-serif jobbing face

Sans-serif and other monotone letters have, however, a functional justification in commercial printing, for they can retain their family characteristics through extremes of all-over thickening, condensing, expanding and so on. The sans-serif designed by the English sculptor Eric Gill is a widely used example of the serious treatment of monotone alphabets with care for legibility. Its adoption as a design family for railway printing caused it to proliferate into 25 design variations under the family name of Gill Sans.

The 20th century has seen eclecticism in type choice conquering the earlier concept of one predominant taste in roman type design succeeding another and rendering it obsolete. In the disciplined book type field, where any queerness or romanticism is fatal, modern designers must compete with the greatest masters of past centuries. Very few new claimants to a place in the book printer's repertory have stood up to that rivalry. In 1932 the *Times* (London) commissioned a roman in the general style that the Dutch letter cutters had evolved for periodical work; i.e., large-appearing, relatively narrow and gaining legibility by the tilted stress of the "old" style. Composing machine manufacturers were permitted to market the face commercially, and its world-wide popularity has made it the nearest approach that an eclectic century has to anything that could be called its own characteristic contribution to history. But modern multiplicity of processes, paper surfaces, different uses for print, to say nothing of the advertiser's constant demand for variety, prevent type design from settling back into the succession of ruling styles and fashions which characterized the centuries in which printing was in effect book printing and used one kind of paper (handmade rag) and one process of multiplication (direct letterpress).

The major languages of scholarship (Greek, Hebrew, Arabic) were exercising European punch cutters from the cradle years of printing, and missionary zeal quickly extended their range. Those nearest to the Latin alphabet, e.g., Russian Cyrillic, have undergone parallel changes in style treatment; Arabic remains purely and stubbornly a calligraphic minuscule. No script among the hundreds which western type foundlers class as "exotics" has achieved the efficiency and adaptability of the roman font with its different member-alphabets—A, a, A, a, A and, where required, "related bold" A, a. It will not replace the other great scripts, but as a supranational vehicle of communication it has no rival.

The word "type" is broadly but legitimately used for the printed letters on the page, which are no longer necessarily the prints of metal types; they may be from metal, rubber or plastic plates which, today, need not have been taken from metal printing types; the images may have been photographically composed onto sensitized film. Hence the designers of new faces for filmsetting will still be type designers, subject to the same discipline where continuous reading is concerned and permitted the same licence in the display field, where film offers new possibilities; e.g., novel alphabets can be quickly produced and distorted at will by the camera. Book faces, however, will require extra forethought. The old engravers, who had, of course, to cut a new set of punches for each successive size, subtly altered the proportions and colour value each time for optical consistency. In filmsetting, one set of master letters may have to serve for every size from footnote 6-point upward, and the best designs for filmsetting will be those which best survive arbitrary enlargement and reduction. But film imposes no other mechanical limitation upon the type designer—to his regret, for he would welcome any such technological challenge as stimulating as that which confronted the pioneer punch cutters.

PRIOR, MATTHEW (1664–1721), English poet and diplomatist, was born in Wimborne, Dorset, July 21, 1664, the son of parents of modest station. His humble origin led to occasional difficulties in his diplomatic career, but did not prevent him from moving in distinguished company all his life. He was educated at Westminster school, where he made friends with Charles Montagu, later earl of Halifax. Both went on to Cambridge, and in 1687 collaborated in a piece of mockery directed at Dryden, *The Hind and the Panther Transvers'd to the Story of the Country Mouse and the Town Mouse*. In 1688 Prior's college, St. John's, elected him to a fellowship, which he retained until his death; but he soon entered diplomacy as secretary to the embassy at The Hague.

Before long he was given responsible positions, and in 1697 was made secretary to the plenipotentiaries at the peace of Rijswijk. Next year he was transferred to Paris as secretary to the embassy.

He had already written a good deal of verse, both formal and occasional; and throughout his life he maintained his output of what he modestly described as "Public Panegyrics, Amorous Odes, Serious Reflections, and Idle Tales, the Product of his leisure Hours, who had Business enough upon his Hands—and was only a Poet by Accident." His lighter poems were marked by an ease, gaiety and grace unsurpassed in English literature. It is for his mastery in this field that he will always be most admired, although he could at times strike a more sombre note with telling effect. Perhaps his masterpiece is the poem known as "Jinny the Just," which remained in manuscript until the 20th century.

In 1699 he returned from France and sat in parliament in 1701 as member for East Grinstead, being also appointed a commissioner of trade and plantations. Soon after the accession of Queen Anne he transferred his support to the Tory party, and became the trusted confidant of Harley (later earl of Oxford) and St. John (later Viscount Bolingbroke). When the Tories came to power in 1710 his diplomatic talents were again employed. He was concerned in the negotiations which led to the peace of Utrecht; and from 1712 until 1714 he again resided at Paris, where he served as plenipotentiary.

After the death of Queen Anne he was recalled, and shared in the troubles which awaited the leading Tories; but despite rigorous examinations he refused to disclose the secrets of the fallen ministers who were his friends. During two years of mild confinement he wrote *Alma, or the Progress of the Mind*, a discursive and often subtle exercise in Hudibrastic metaphysics. In 1718 he published a stately folio of his collected poems, including *Alma* and his other long poem *Solomon on the Vanity of the World*, a didactic work completed at least a decade earlier. He passed his last years mainly with Lord Oxford, by whose family and household he was greatly beloved. Oxford bought for him a small property in Essex, Down Hall, to which he grew much attached. But his health had never been robust; and he died at Oxford's seat, Wimpole in Cambridgeshire, on Sept. 18, 1721.

As a diplomatist Prior proved himself an excellent negotiator, adroit, resourceful and clear headed. He was gifted with a personal charm and a sweet temper uncommon among the wits of his age. Most contemporary references to him are kindly, and he was fortunate in his friends in every walk of life. He never married, but maintained relations with various women from humbler circles than those in which he habitually moved. Little is known about them; but they included the much-loved Jinny, the subject of his most tender and moving poem.

Eves, *Matthew Prior: Poet and Diplomatist* (1939).

(R. W. K.-C.)

PRIOR, a title applied generally to certain monastic superiors. Under the Roman Empire the word *prior* signified "ancestor." In the early Middle Ages it was commonly applied to secular officials and magistrates, and it remained all through the Middle Ages as the title of certain officials in the Italian city-states.

In the Rule of St. Benedict and other early rules the title "prior" indicated in a general way the superiors and elders in a monastery; afterward the title was restricted to the abbot's vicegerent, who was generally charged with the disciplinary details of the monastery. With the foundation of the Order of Cluny in the 10th century there appeared the conventual prior, who ruled as head of a monastery.

In modern times "conventual prior" denotes the head of a self-governing house that has not been erected into an abbey, "simple" or "obedientary prior" denotes the superior of a house that is dependent on an abbey. A "claustral prior" is one who acts as deputy to an abbot. The title "prioress" is used similarly. A monastery headed by a prior or prioress is called a priory.

PRIPET MARSHES (POLESYE) form the largest tract of swamp in Europe and lie in the U.S.S.R. in the basin of the Pripyet, or Pripyat, River, a tributary of the Dnieper. They cover the greater part of Brest and Gomel *oblasts* of the Belorussian Soviet Socialist Republic and the northern parts of Volyn, Rovno, and Zhitomir *oblasts* of the Ukrainian S.S.R., an estimated 10,000,000 ac. (4,000,000 ha.). Into the flat Pripyet Basin flow a number of rivers from the White Russian ridge to the north and the Volyno-Podolsk upland to the south. The deposition of fluvio-glacial sands complicated the drainage, and man contributed to the formation of swamps by building fish and milldams. There are small areas of sphagnum peat bog, but the swamps are for the most part reed or grass marsh or swamp-forest associations with willow and alder. The only dry areas are "islands" formed by sand dunes or by remnants of a former, higher river terrace. In 1872 drainage of the swamps was started by a state-organized "western expedition for the drainage of swamps," led by I. I. Zhilinski. Over the next 25 years more than 3,000 mi. (4,828 km.) of canals were built and extensive areas were reclaimed. During World War I and the following years, when the region was divided politically between Poland and the U.S.S.R., much of this work was destroyed or fell into disuse. After 1939 further drainage operations were undertaken. The chief towns of the marshes are Mozyr in the east and the seats of ancient princedoms, Turov and Pinsk, all on the Pripyet River. (R. A. F.)

PRISCIAN (PRISCIANUS CAESARIENSIS) (fl. c. A.D. 500), the best-known of all the Latin grammarians, author of the *Institutiones grammaticae* which, together with the work of Aelius Donatus, had a profound influence on the teaching of Latin and indeed of grammar generally in Europe. He was born at Caesarea in Mauretania (the modern Cherchel in Algeria), but taught in Constantinople. His minor works include *De nomine, pronome et verbo* ("On Noun, Pronoun and Verb"), an abridgment of part of the *Institutiones grammaticae*; *Partitiones xii versuum Aeneidos principalium* ("The Parsing of the First 12 Verses of the *Aeneid*"), for the teaching of grammar in schools; a treatise on weights and measures; a treatise on the metres of Terence; *Proexercitamina*, an adaptation for Latin readers of some Greek rhetorical exercises; a panegyric in verse on the emperor Anastasius I (see E. Bährens, *Poetae Latini minores*, vol. v. 1883); and a verse translation of Dionysius' *Periegesis* (see the critical edition by P. van Woenstijne, 1953). Priscian's *Institutiones grammaticae* ("Grammatical Foundations") is a systematic exposition of Latin grammar. Of the 18 books into which it is divided, the first 16 deal mainly with sounds, word-formation and inflexions; the last 2 (which form nearly one-third of the whole work) with syntax. As far as possible Priscian takes the works of Apollonius Dyscolus on Greek grammar as his guide. He draws illustrative citations from many Latin authors and has thus preserved numerous fragments which would otherwise have been lost (for the text of the grammatical works see H. Keil, *Grammatici Latini*, vol. ii and iii, 1855-59).

Priscian's work was quoted by Aldhelm in the 7th century and by Bede and Alcuin in the 8th, and was much used by Rabanus Maurus and by Servatus Lupus of Ferrières in the 9th. Subsequently it became the standard work for the teaching of grammar in the medieval schools; and it provided the background for the rise of speculative grammar (the logic of language) in the 13th and 14th centuries. There are about 1,000 manuscripts extant. Of these, the greater part contain only books i-xvi (called *Priscianus minor*); a few contain books xvii and xviii (*Priscianus maior*); and some of the minor works; and a few contain all 18 books of the *Institutiones*. Apart from fragments, the oldest manuscripts are of the 9th century. The first printed edition was that of 1470 at Venice.

(R. H. R.)

PRISCILLIAN (c. 340-385), the first person in the history of the church to suffer death for heresy, was a Hispano-Roman champion of rigorous asceticism and founder of a party in the

Spanish Church that persisted into the 6th century. Cultured and wealthy, he acquired a reputation for strictness of life and *c.* 375 began, as a layman, to propagate in and around Mérida and Córdoba a doctrine of absolute renunciation of all sense pleasures. Two bishops, Instantius and Salvian, and numerous other persons joined him and were guided by him, in a sort of secret society, in the search for higher perfection, condemning, *e.g.*, marriage and the use of wine and flesh meats. Before long such groups were found throughout western and southern Spain and in southern Gaul, and the whole Spanish Church was disturbed. The local hierarchy suspected that the new movement was Manichaeism in character (*see* MANICHAISM). Hyginus, bishop of Mérida, and Ithacius, bishop of Ossonoba, were its leading opponents.

The Council of Saragossa (380) condemned certain ideas attributed to Priscillian, who, nonetheless, was elected bishop of Avila. The emperor Gratian was persuaded by Priscillian's enemies to decree the banishment of all "Manichaeans," whereupon Priscillian, Instantius and Salvian went to Italy, where Salvian died. They were not received by Pope Damasus I or by Ambrose of Milan, but they contrived the revocation of their banishment and were then able to force Ithacius to leave Spain. He went to Trier, seat of the pretorian prefecture in which Spain lay, and when in 383 the usurper Maximus made Trier his capital, Ithacius persuaded him to have Priscillian and Instantius tried. This was done in 384 by a synod at Bordeaux, and they were condemned. Priscillian appealed to Maximus; the latter had him taken to Trier, where, in the criminal courts, he was judged guilty of sorcery and immorality and was executed.

The fall of Maximus in 388 led to a reaction in favour of Priscillianism; Ithacius and some others who had opposed Priscillian were deposed and exiled. The Spanish Church continued to be divided, Galicia and the west being Priscillianist strongholds. In 400 and 447 councils at Toledo condemned certain of Priscillian's doctrines, and in 407–408 the emperor Honorius proscribed them, but the barbarian invasions prevented effective repression. In 561 the Council of Braga renewed the condemnation, and thereafter Priscillianism as an organized cult disappeared.

The question of Priscillian's orthodoxy has been much discussed. G. Schepps discovered and published (1889) 11 treatises which he assigned to Priscillian (though careful study convinced G. Morin in 1913 that their author was really Instantius) and which, though they do not clearly indicate whether the writer held Manichaean views, make plain his unorthodox doctrine of the Trinity, in which the Son differs from the Father only in name. The excitement aroused in Spain and Gaul and the vigorous opposition from outstanding contemporaries are inexplicable if Priscillian was merely an orthodox ascetic resented by worldly prelates.

See A. d'Alès, *Priscillien et l'Espagne chrétienne à la fin du IV^e siècle* (1936); Stephen McKenna, *Paganism and Pagan Survivals in Spain up to the Fall of the Visigothic Kingdom*, pp. 50–74 (1938). (A. G. B.)

PRISM, in geometry, a polyhedron (multifaced solid) having two of its faces, known as bases, congruent (identically equal) polygons in parallel planes, and the other faces parallelograms equal in number to the sides of the bases. The faces, excluding each base, are called the lateral faces, and the intersections of these faces are called the lateral edges, being all equal. The perpendicular distance between the planes of the bases is called the height or altitude of the prism. If the lateral edges are perpendicular to the planes of the bases, the prism is called a right prism;

if they are oblique to these planes, it is called an oblique prism. Prisms are said to be triangular, quadrangular, pentagonal and so on according as their bases are triangles, quadrilaterals, pentagons and so on. A prism having parallelograms for its bases is called a parallelepiped. If the bases and lateral faces are all rectangles, it is called a rectangular parallelepiped. The part of a prism included between the base and a section made by a plane oblique to the base is called a truncated prism. A geometric solid that has for its bases two polygons in parallel planes, and for its lateral faces triangles or trapezoids (trapezia) with one side in one base and the opposite vertex or side in the other base, is called a prismoid, a prism being a special case. (In optics the word denotes a triangular prism.) The volume of a prism of base B and altitude a is aB ; of a prismoid with bases B and B' , altitude a and area of a mid-cross section M , is $\frac{1}{2}a(B + B' + 4M)$.

See BINOCULAR INSTRUMENT; CRYSTALLOGRAPHY; REFRACTOMETER; SOLIDS, GEOMETRIC; and references under "Prism" in the Index.

PRISMOID, a solid bounded by any number of planes, two of which are parallel and contain all the vertices. The two parallel faces are called the bases.

PRISMOID

The volume V of such a solid was found by the self-taught mathematician Thomas Simpson (1710–61) as follows: Let M be a section made by a plane parallel to the bases B and B' and midway between them, and let h be the distance between the bases.

Then $V = \frac{1}{2}h(B + B' + 4M)$, a formula frequently used in finding volumes and applicable to most of the elementary geometric solids, and in general to any solid bounded by a ruled surface and two parallel planes. (P. DU V.)

PRISON. In the United States, where crime rates have long been among the highest observed in modern societies, there are well over 200,000 prisoners confined in more than 200 state and federal prisons and reformatories, with an annual increase in the prisoner population of approximately 4,500. The cost of constructing the required housing for this growing population approaches \$45,000,000 per year. Current trends indicate that in the foreseeable future the number of prisoners and the related financial expenditures will continue to increase.

Two-thirds of the criminals committed to penal institutions in the U.S. have prior criminal records. Of all prisoners 98% are returned to civilian life after an average stay in most institutions of well under three years. Evidence from police, court, and parole files suggests that nearly half of the persons discharged from penal institutions return to careers in crime and in most cases within a year after release. Generally, the longer an offender has been confined in prison and the more times he has been committed, the higher the probability of his continued criminality.

The above findings have prompted many criminologists to re-examine the defects and virtues of the prison system in the search for more effective methods of crime control. Prisons, in other words, are now being subjected to the same critical scrutiny that earlier resulted in the substitution of imprisonment for previous methods of crime control.

Few persons realize that the prison system as it operates in nearly all parts of the world is largely an American development having its main origins late in the 18th century. The evolution of the prison system was primarily the consequence of the growth of new philosophies of human conduct. Prominent in this connection was the decay of faith in earlier methods of retributive vengeance designed to eliminate the criminal offender, ostracize him, or permanently stigmatize him. Concurrent with the decline of vengeance there developed a conception of rational man which assumed that criminal human behaviour can be regulated by a system of lesser punishments administered in an objective and impersonal manner by specialized agencies of government. The official punishments now used with greatest frequency are fines and various terms of imprisonment.

Just as expressions of vengeance against the offender have

TYPES OF PRISMS: (A) RIGHT; (B) OBLIQUE TRIANGULAR; (C) TRUNCATED; (D) RECTANGULAR PARALLELEPIPED

largely given way to a system of punitive confinement, so are current punitive practices gradually being minimized in favour of a new philosophy of therapy and rehabilitation. This shift in emphasis from vengeance to impartial punishment and then to therapy is the general principle that seems to have guided the development of the modern prison system.

MAJOR HISTORICAL DEVELOPMENTS

Prior to the 19th century, basic methods of crime control were designed to exclude the offender from the affairs of the community or to identify him publicly so that other persons could protect themselves in their dealings with him. Major devices used for these purposes were corporal punishment, disfigurement, exile, or execution of the offender. Decreasing use of these measures in the past few centuries is closely associated with the development of the prison system.

Forms of Crime Control.—Corporal Punishment.—Early Babylonian law developed the principle of *lex talionis* which asserted that criminals should receive as punishment precisely those injuries and damages they had inflicted upon their victims. Many societies applied the "eye-for-an-eye and tooth-for-a-tooth" principle quite literally in dealing with the offender. This principle still serves as a partial basis for the assessment of fines against minor offenders. Through the 18th century it provided rationale for the corporal punishments, e.g., flogging, branding, mutilation, and the stock and pillory, that were commonly used in those instances that did not call for the death penalty or exile.

Some vestiges of extreme and brutal punishments still exist in some societies. The whipping post, for example, may be seen in the United States, in Delaware, although no floggings have been reported there since 1952. In Scotland, England, and Wales the public whipping of criminals is still prescribed by law, but was greatly limited by the Criminal Justice Act of 1948. Again, Delaware, as late as 1905, also used the pillory (q.v.), although England, France, and the U.S. federal government abolished its use before 1840.

Branding of criminals was fairly common in some Oriental societies within the past century and was not finally discontinued in England for army deserters until 1879. Similar penalties were also frequently administered in the American Colonies but were replaced before the American Revolution by badges, such as the "scarlet letter" of the adulteress, which law violators were required to wear. Nazi Germany in the 1940s used both a form of branding with tattoo marks and badges in its persecution of the Jews.

The public demand that physical injury should be inflicted upon the criminal has by no means been eliminated and periodic attempts are still made to reinstitute various forms of corporal punishment, especially for juveniles and petty offenders. It nevertheless seems apparent that there has been a drastic reduction in the amount of confidence placed in such methods of retaliation against the criminal and that these devices of social control are progressively being abandoned in most civilized societies. One of the results of this trend has been an increased use of imprisonment.

Transportation.—Another traditional method of crime control now in disfavour in most countries is transportation, a punishment involving the removal of the offender from his own society to a distant penal colony or camp where he is engaged in forced labour. Exile, transportation, and banishment, like corporal punishment, have an ancient origin. They have been observed in certain preliterate societies, sometimes under conditions that made survival of the offender highly problematic. Early Greeks and Romans dispatched their criminals to mines and quarries or put them to sea as galley slaves. The employment of criminals in various kinds of forced labour (q.v.) continued in several countries until modern times. (See also DEPORTATION AND EXILE.)

A score of nations in Europe and Latin America transported their criminals to widely scattered penal colonies. However, penal colonies achieved their greatest development among the English, French, and Russians. England, for example, shipped criminals to America until the Revolution and to Australia into the middle

of the 19th century. France established penal colonies in Africa, New Caledonia, and French Guiana. Some of the Guiana colonies including the notorious Devil's Island, were still operating during World War II when they were abolished by the Free French government. The U.S.S.R. maintained penal colonies in Siberia for political criminals and certain other types of offenders. Though initially organized under the tsars, the Siberian colonies reached their greatest expansion from the Revolution through the Stalin era. Most governments have discontinued the large-scale transportation of criminals.

As long as penal colonies were operated at a great distance from the home country, there was relatively little public concern for the standards of health, decency, and welfare that prevailed in these communities of criminals. But the barrier of distance has been continuously reduced by modern communication facilities, making it increasingly difficult for urban industrial nations to maintain isolated colonies. Further, opposition to such colonies has been encouraged by the doctrines of democracy that have become more meaningful in many parts of the world. As a consequence most governments, instead of relying upon physical distance as a means for isolating their convicted criminals, find it advisable to create alternative techniques of crime control. Some of the alternatives used for segregating offenders or for supervising them in the community where their social productivity is usually at a maximum are provided by penal institutions and by the greatly increased use of probation and parole (q.v.).

Capital Punishment.—The third major ancient form of crime control that has shown a steady decline is capital punishment. The execution of a criminal, which a century ago was not an uncommon public spectacle attended by much brutality and torture, has been abolished in many parts of Europe and South America. France (which rarely imposes it) and the United States remain among the chief Western powers that continue the use of the death penalty. Even so, a number of U.S. states have abolished this form of punishment. England, after a 1957 law greatly restricted imposition of the death penalty, abolished it in 1964. (See also CAPITAL PUNISHMENT.)

Certain other trends in the use of capital punishment suggest that it will continue to decline. Except for cases of treason and some infractions of military discipline, there has been a marked reduction in the number of offenses that call for the death penalty. In most jurisdictions it can be legally invoked for only a few of the most serious crimes such as murder, kidnapping, and forcible rape, and even in cases involving these offenses there has been a strong tendency toward the elimination of compulsory executions and toward making the punishment subject to the discretion of the court and the jury.

De-emphasis of capital punishment is further reflected in the many legal restrictions that generally prohibit the public from attending executions. Likewise, the earlier gruesome methods of capital punishment have in many places been replaced by less spectacular and comparatively painless methods, including the use of the gas chamber (q.v.) and electrocution.

The above trends mean that capital punishment is very rarely used in any modern society as a device for the control of traditional crimes. Execution may be used for political purposes or for ideological reasons, as was the case in the deep South of the U.S. and in the attempted elimination of the Jews by Nazi Germany (see LYNCHING AND LYNCH LAW; GENOCIDE). But execution of the criminal has become the exception rather than the rule. In the U.S., for example, about 50 capital offenders are executed each year although the number of such offenses reported exceeds 8,000. Thus, the abolition of the death penalty would have little effect upon the number of prisoners or the cost of maintaining the prison system.

Development of the Prison System.—Although the decline of ancient methods for handling criminals has no doubt been important, there are other more positive factors that have influenced the rise of the prison system. Some of these factors can be indicated by a brief review of the history of penal institutions in Western culture.

Jails were widely used in 12th-century England as places for

COURTESY OF THE ILLINOIS STATE PENITENTIARY
CIRCULAR CELL HOUSE ADAPTED FROM BENTHAM'S "PANOPTICON" AT STATEVILLE PRISON, JOLIET, ILL., PERMITS GUARDS IN THE CENTRAL TOWER TO KEEP WATCH ON EVERY CELL

sponsored a law providing for two penitentiaries that would house inmates in solitary confinement at night and congregate them during the day for hard labour. For various reasons this law was never implemented. About 20 years later plans were developed for the construction of a "panopticon" designed by Jeremy Bentham (q.v.). The panopticon, a circular, glass roofed, tank-like structure with cells along the external wall facing toward a central rotunda, made it possible for officers stationed in the rotunda to keep all of the inmates under constant surveillance. Although Bentham's novel idea was not incorporated in the plans for penal institutions built at that time, its design had some influence on future construction. For example, a prison incorporating the essential features of the panopticon was erected in the

the confinement of accused persons until their cases could be tried by the king's court. In 1166 Henry II commanded that every county should establish an institution for this purpose.

Imprisonment gradually came to be accepted not only as a device for holding persons awaiting trial but also as a means of punishing convicted criminals. During the 16th century a number of houses of correction were established in England and on the continent for the reform of minor offenders. In these institutions there was little segregation by age, sex, or other condition. The main emphasis was on strict discipline and hard labour. In England an act of 1711 fixed the maximum term of confinement at three years.

Among the best known of the houses of correction, the immediate forerunners of the prison, were London's famous Bridewell (q.v.) and the Ghent House of Correction, which were established in 1553 and 1775, respectively. Similar institutions were constructed in the American Colonies soon after their settlement.

Although reformation of offenders was intended in the houses of correction, the unsanitary conditions and lack of provisions for the welfare of the inmates soon produced widespread agitation for further changes in methods of handling criminals. Leading agitators included Montesquieu, Voltaire, Thomas Paine, Diderot, Adam Smith, Bentham, Sir Samuel Romilly, John Howard, and Elizabeth Fry. These leaders painstakingly exposed and publicized the conditions of filth and immorality that prevailed in the houses of correction which, they charged, instead of reforming their inmates, actually fostered crime and disease. For example, John Howard (q.v.), spent the years 1778-90 traveling throughout Europe in search of more effective correctional practices. He carefully chronicled his experiences and in this way educated the public with respect to the conditions he observed. Several of his observations had great impact upon subsequent developments in the field of correction. He was favourably impressed by the administration and the architectural design of the Ghent House of Correction, and by the Papal Hospice of Saint Michael in Rome, an institution that cared for errant boys; founded in 1703 by Pope Clement XI, it may have been the first correctional institution to house inmates in solitary confinement. Both Ghent and Saint Michael segregated several classes of inmates, housed them in separate cells, and provided for their employment at hard labour.

Solitary Confinement—Solitary confinement of criminals was especially appealing to the rationalists of the 18th century because they believed that solitude would help the offender to become penitent and that penitence would result in reformation. Thus in England in 1779 William Blackstone and William Eden

U.S. at Stateville, near Joliet, Ill., nearly 150 years later.

The next important steps in the evolution of prisons occurred in the United States. Pennsylvania's constitution of 1776 embodied certain principles that had been enunciated by William Penn and the Quakers a century earlier. Fines and imprisonment became the major forms of punishment for nearly all offenses, felonies as well as misdemeanours. By 1794 murder remained the state's only capital offense. At about that time, Walnut Street Jail in Philadelphia was converted to become the first state penitentiary; a small number of cells were added to house the most serious offenders and prisoners were segregated by sex and the severity of their offenses. Furthermore, debtors and witnesses were separated from convicted criminals. Hard labour was stressed as a reformatory measure, except for the most serious offenders who were kept in complete isolation.

Separate System.—Solitary confinement received far greater emphasis when Eastern State Penitentiary, an institution especially designed for the separate confinement of prisoners, was opened on Cherry Hill in Philadelphia in 1829. Seven blocks of cells radiated like the spokes of a wheel from a central rotunda. The cells were 16 ft. high, nearly 12 ft. long, and 7½ ft. wide. Attached to each cell was an exercise yard, completely enclosed to prevent contact among the prisoners. The prisoner remained in his cell or his yard and saw no one except the officers of the institution and an occasional visitor from outside. Initially, it was planned that the prisoners would have no employment, but this was modified because of the disastrous experience with inmate idleness at Western State Penitentiary, opened three years earlier at Pittsburgh. Under the new plan materials were brought to the cell where the prisoner worked alone at trades such as weaving, tailoring, carpentry, or shoemaking.

This method of prison management, known as the "separate system," became a model for penal institutions constructed in several other states and in various parts of the world. Through much of the 19th century the separate system remained the dominant philosophy of prison management in much of Europe.

Silent System.—Meanwhile, strenuous opposition to the prolonged isolation of prisoners developed very early, especially in the U.S. Even before Eastern State Penitentiary was placed in operation, its critics had been successful in formulating a competing philosophy of prison management, known as the "silent system." A model prison was constructed at Auburn in New York to implement the various features of the new system, which was instituted by 1825.

Cells in Auburn Prison were very small compared with those at Eastern State, measuring only 7 ft. long and 3½ ft. wide. Two

rows of cells were placed back to back along the center of a long and narrow cellblock, each row being separated from the exterior wall of the building by a corridor used for traffic. Light and air entered through small windows in the cell doors and in the exterior walls of the cellblock.

The main distinguishing feature of the silent system was that prisoners were allowed to work together in the daytime. Silence was strictly enforced at all times, however, and at night the prisoners were confined in individual cells. To and from their workshops the prisoners were required to walk in line and do the lockstep, a slow and rhythmic shuffle in which each person placed one hand on the shoulder of the man in front of him.

Vigorous competition between supporters of the silent system and of the separate system prevailed until about 1850, but by that time the Auburn plan had been victorious in most U.S. states. During this period new developments in Europe and elsewhere were beginning to produce fundamental revisions in both U.S. systems.

Mark System.—The mark system was developed about 1840 by Captain Alexander Maconochie at Norfolk Island, an English penal colony located east of Australia. Instead of serving fixed sentences, prisoners there were required to earn marks or credits proportional to the seriousness of their offenses. Credits were accumulated through good conduct, hard work, and study, and could be denied or subtracted for indolence or misbehaviour. When a prisoner obtained the required number of credits he became eligible for release.

The mark system symbolized the decline of the "let the punishment fit the crime" theory of correction and presaged the use of indeterminate sentences, individualized treatment, and parole. Above all it emphasized training and performance, rather than solitude, as the chief mechanisms of reformation.

Irish System.—Further refinements in the mark system were developed in the middle 1800s by Sir Walter Crofton, director of Irish prisons. Irish inmates progressed through three stages of confinement before they were returned to civilian life. The first portion of the sentence was served in isolation. Then the prisoners were allowed to associate with other inmates in various kinds of work projects. Finally, for six months or more before release, the prisoners were transferred to "intermediate prisons," small portable institutions where inmates were supervised by unarmed guards and given sufficient freedom and responsibility to permit them to demonstrate their fitness for release. In addition, release was conditional upon the continued good conduct of the offender, who could be returned to prison if this seemed advisable.

Reformatory Movement.—*United States.*—Many features of the Irish system were adopted by reformatories constructed in the U.S. in the late 19th century for the treatment of youthful and first offenders. Among the leaders of the reformatory movement was Zebulon Brockway, first superintendent of New York's Elmira Reformatory, opened in 1876. Brockway and his associates advocated classification and segregation of various types of prisoners, individualized treatment emphasizing vocational training and industrial employment, indeterminate sentences and rewards for good behaviour, and parole or conditional release. The reformatory philosophy gradually permeated the entire U.S. prison system. By the turn of the century isolation and solitary confinement were used primarily as disciplinary actions against recalcitrant prisoners instead of being justified as effecting penitence and reformation.

Europe.—The Irish system and the U.S. innovations had great impact upon European correctional practices. England's famous Borstal System (*q.v.*), for example, was established in 1903 by Evelyn Ruggles-Brise, director of English prisons, after he had studied several U.S. reformatories. The Borstal System is comprised of a variety of institutions, each providing a specified degree of custodial supervision and specializing in a certain kind of training and treatment for young offenders. Individualized treatment also is provided in the period immediately following release. The chief objective is no longer to punish the offender but to develop his capacity to assume full responsibility for his conduct. The use of recreational, employment, and educational resources and

facilities in the outside community is an essential feature of the Borstal System (*see also REFORMATORY*).

Trends.—Correctional institutions in a little more than 150 years have almost completely rejected the doctrine of solitude and penitence. Contemporary penal institutions, however, are not guided by any uniform philosophy. Correctional programs in nearly all parts of the world evidence a significant trend toward specialization, diversification, and experimentation. Rapid changes in the design and construction of correctional facilities in their treatment programs and even in their major objectives make it difficult to describe modern institutions in general terms or to anticipate future developments. Certain practices and tendencies may nevertheless be cited as important departures from penal tradition.

Probation and Parole.—Considerable effort, for example, is aimed at the rehabilitation of prisoners and at minimizing their numbers. Minor offenders are sometimes allowed to pay fines in installments, or to serve jail sentences at night or on weekends. The expanding use of probation and parole (*qq.v.*) as rehabilitative procedures also tends to hold down the numbers of inmates in institutions. Other programs include the use of residential community centres, or halfway houses, preceding parole; granting brief leaves, or furloughs, in emergencies or for preparations for release; and work release for private employment or vocational training in the community: in the U.S. these were authorized by the federal Prisoner Rehabilitation act of 1965.

Specialized Treatment.—A second important trend is the substitution of individualized treatment for the earlier doctrine of equal punishments for equal crimes. Indeterminate sentences and segregation of offenders according to their backgrounds and personality characteristics are prevalent in nearly all countries. More reliable methods of diagnosis and classification, largely based on advancements in social and medical sciences, frequently make it feasible to prescribe special treatment relevant to the needs of the individual offender. Increasingly, specialized treatment includes professional counseling and psychotherapy, and various forms of medical care, as well as the more conventional literacy programs and academic and vocational training. The acceptance and use of such treatment programs indicate that social work, psychiatry, and the behavioural sciences will have much greater impact upon the field of correction than they have had in the past.

Specialized treatment programs encourage the diversification of correctional institutions. Ideally, this means each institution should maintain programs specifically designed for certain types of offenders. Some diversification has long been practised, as reflected in the conventional separation of offenders by age and sex. However, current trends are reflected in the establishment of separate institutions for various categories of offenders, such as drug addicts, alcoholics, sex psychopaths, and criminals who are mentally ill. Such diversification is characteristic of the U.S. Federal Bureau of Prisons and the correctional facilities of the state of California. The Scandinavian countries also operate a number of prison hospitals where selected sex offenders may be either castrated or given hormonal treatment. Again, nearly all prison systems provide special facilities for inmates who need either maximal or minimal custodial supervision. Treatment programs in "escape-proof" penitentiaries that house dangerous criminals and habitual offenders (*q.v.*) are vastly different from those in maximum custody farms and camps. Most of the newer facilities have been penal farms, forest camps, and small cottage-style institutions designed to provide individualized treatment for offenders who do not require a high degree of custodial control.

Social Rehabilitation.—The third major trend in prison administration involves an attempt to reduce the social barrier between inmates of the correctional institution and the civilian community. Programs widely used to encourage social participation among inmates and members of their families or groups of citizens who are particularly interested in the field of correction include more liberal policies governing visits, letter-writing privileges, and self-improvement classes. Debating societies, study and discussion groups, and therapeutic agencies such as Alcoholics Anonymous have regular contacts with prison inmates. Sweden

and several other European countries have instituted frequent furloughs for home visits and sometimes have provided outside employment for selected prisoners. Soviet Russia has allowed certain offenders to settle with their families in industrial colonies largely populated by convicted criminals. Mexico, Russia, and several other countries have permitted conjugal visits in some of their prisons, a practice intended to alleviate the sexual problem that is universally present in penal institutions.

In addition, other programs are aimed at increasing public interest and participation in prison management. England, for instance, has developed a system of official visits that brings citizens into the institution to assist in the resocialization of the offender and to insure public acceptance of the institution's programs and policies. Similarly, advisory councils of private citizens are widely used for the same purposes in the United States and elsewhere. These councils can provide some of the technical and professional assistance necessary for maintaining adequate standards in prison educational and vocational training programs, industrial operations, recreation, and religious instruction. They also serve as effective instruments for public education regarding prison problems and issues. These developments indicate a growing recognition of the important role played by the civilian community in the rehabilitation of the prison inmate.

Group Therapy in the Prison Community.—A fourth trend is the increasing interest in the possibility that the society formed by the prisoners can be utilized for therapeutic purposes. In the final analysis, the social organization of the prisoners, the prison milieu, may have greater impact upon inmate attitudes and activities than do the various programs previously mentioned. Improved diagnosis and extensive use of small institutions have encouraged the assignment to the inmates themselves of responsibility for their own welfare. Group therapy, it is held, may offer a mechanism by which selected prisoners can be trained to make decisions and accept responsibility for their own conduct.

As practised in the U.S. at Highfields in New Jersey and in the prisons of California, group therapy involves some important differences from the system of inmate self-government that was tried unsuccessfully by Thomas Mott Osborne at Auburn Prison in 1913. It is held that group therapy may give inmates an opportunity to participate more actively in some of the routine affairs of the official prison community instead of being merely passive recipients of rules and regulations. It is believed this may help to develop a greater sense of social responsibility among some of the prisoners. Strict limits are nevertheless placed on the scope of inmate responsibility, and group therapy in no way restricts the authority or responsibility of prison officials. While the preliminary results have appeared to be very promising, the long-run effectiveness of group therapy cannot yet be clearly ascertained.

Professional Personnel.—Finally, the fifth significant trend in correction is the development of prison employment as a career service. Merit systems and civil service have been established in many parts of the United States and in much of Europe. Professional training is required of many prison employees, especially in programs of inmate classification, education, medical care, and therapy. Specialized courses of training are offered by an increasing number of colleges and universities. Criminology (*q.v.*) has for some time been regarded as a specialty within the disciplines of sociology, psychology, or social work, and the University of California has instituted a fully accredited Graduate School of Criminology.

The trend toward professionalization of correctional occupations is still in its infancy, however. As of the 1960s, for example, only a dozen of the U.S. states employed full-time psychiatrists in their prisons and reformatories; and of the total number employed, nearly half were attached to the prison system of the state of California. In other words, there were nearly 6,000 prisoners for every psychiatrist employed in U.S. penal institutions. Further, fewer than 500 social workers and sociologists were employed by state institutions, making an average case load of about 380 prisoners per employee in this essential service. It seems clear that a considerable increase in the number of profes-

sional workers is required if the efficacy of techniques of prison therapy is to be established and the achievement of the objectives of such therapy attained. The fact remains that the personnel having the most intimate day-to-day contact with the prisoners, the guards in most prisons, are appointed through the political spoils system rather than through civil service.

An Emerging Philosophy.—The above cursory review of modern correctional history suggests that beliefs concerning the causes of crime and the best methods of crime control are being revolutionized for the third time within the past few centuries. In the late 18th and early 19th centuries the philosophy of rational man resulted in the substitution of imprisonment for the earlier methods of corporal punishment. Then the late 19th and early 20th centuries saw a decline in rationalism and the development of individualized treatment programs based on the assumption that criminals suffered from major mental, emotional, or social deficiencies and emphasizing education, casework, and psychiatry.

Again, an accumulation of evidence contradicted the dominant philosophy of the time: the number of crimes increased at an alarming rate; studies of the effects of individualized treatment were frequently discouraging; law violations came to be recognized as group or gang activities rather than solitary deeds; many law violators revealed few signs of the expected personal inadequacy. It was perhaps inevitable that another new conception of crime and its treatment should come into prominence.

There is some rather convincing evidence that society is in the early stages of a third major revolution in its beliefs concerning crime and correction. The chief feature of the rising philosophy is the idea that society is the patient in need of corrective action if crime control is to become a reality. Various kinds of unconventional behaviour are sometimes richly rewarded. Wealth, power, and prestige are frequently highly regarded irrespective of the means by which they may have been attained. Political corruption and white-collar crime are too often viewed as unavoidable nuisances (*see CRIME*). Respected and influential citizens may be favourably disposed toward illegitimate activities provided there are sufficient material benefits and good prospects for escaping detection or censure. These are some aspects of crime and deviant behaviour that have recently attracted the systematic attention of correctional experts.

Current explanations of criminal behaviour tend to place more emphasis on the compelling pressures exerted upon any given person by others in his community and the social groups to which he belongs. These pressures reflect a culture that prescribes his goals and his standards of conduct and a society that regulates the various means and mechanisms that are accessible to him in his efforts to achieve his objectives. This does not deny individual differences or a sense of personal responsibility, but it does assert that a given person's behaviour cannot be realistically analyzed or evaluated without taking into account his social and cultural milieu.

This rising philosophy has some important implications for prisons and correctional programs. It maintains that treatment and therapy cannot be foisted upon resistive and suspicious prisoners. Treatment is a dynamic process that requires the cooperation and active participation of the offender if it is to be successful. Therefore the main objective of the prison should be to get the inmates to participate actively in a smoothly functioning organized society, perhaps at first in the prison setting, and then later in the broader community. This, in fact, would seem to be one of the main functions of the correctional program. Illustrations of its application include group therapy as it is practised in prisons and in the supervision of probationers and parolees, milieu therapy in small institutions, inmate advisory councils, home visits, and prisoner furloughs. These approaches are supported by Alcoholics Anonymous and other organizations that appeal to large numbers of former prisoners; halfway houses that help diminish the abrupt shift from prison existence to life in the free community; and the use of citizens' advisory councils and committees in the management of prison programs. All these devices are designed to reduce barriers between the prison and civilian communities and to increase social interaction between inmates and others.

Despite the new attitudes toward crime and correction, the beliefs of the past two centuries have by no means been eliminated. Indeed the most striking characteristic of the typical prisons of today is that they tend to serve as the scene of conflict among the three more or less distinctive philosophies mentioned above. This is the problem to which we now turn.

PRISON ADMINISTRATION AND THE ORGANIZATION OF THE PRISON COMMUNITY

Prison officials carry a public trust. Their duties and responsibilities are defined by the community in terms of conventional beliefs and attitudes. If their policies and objectives deviate very far from those of the broader society, correctional officials encounter serious public opposition. An essential task for the correctional administrator is the assessment of public opinion. To the extent that public beliefs and attitudes are confused or contradictory, it may be expected that prison programs and policies will reflect these discrepancies.

Objectives.—The foremost objective of prison administration is the maintenance of control over the inmates and the prevention of escapes and riots. The most grievous difficulty the prison administrator is likely to face is the breakdown of official authority due to inmate uprising or conspiracy. Other objectives such as therapy, deterrence against potential offenders, and the reinforcement of cultural norms or standards are generally relegated to positions of less importance. Furthermore, the great interest in custodial problems such as escapes and riots means that even those institutions that are oriented toward the treatment of the offender are likely to evaluate their programs in terms of the frequency of custodial incidents. Regardless of the verbal support given to therapy and related functions by correctional administrators, it is clear that public evaluations of prison administration are still largely determined by matters dealing primarily with custody.

Not only the objectives of correctional institutions but also the policies aimed at their attainment are greatly influenced by conventional beliefs and assumptions. Here again there is conflict between the old and new philosophies. Crime is usually interpreted as deliberate misconduct and prisoners consequently are expected to be belligerent and unruly if they can get away with it. Strict surveillance and punitive actions are generally deemed necessary to show the prisoner that society is stronger than he is, serve as a lesson for potential troublemakers, and promote respect for law and order. It is maintained that prisons should have police powers sufficient to detect and to punish any violations of rules and regulations. Treatment is commonly viewed as the inculcation of useful habits, such as thriftiness and industriousness, and the acquisition of social and occupational skills. Moreover, prison officials are held solely accountable for the attainment of correctional objectives while, according to the usual public view, the inmates are pretty much absolved of any responsibilities.

Maxims such as those mentioned are deeply rooted in contemporary culture. They rationalize and give direction to prison programs and policies and serve as the basic operating assumptions for most prison programs. They also inevitably reflect some of the discrepancies that are inherent in conventional beliefs concerning crime and correction. These maxims hold penal officials responsible for the conduct of their prisoners, for example, while at the same time they encourage the expectation that the prisoners will learn self-reliance and a sense of responsibility. Again, the maxims claim that prisoners are sure to display disobedience, but at the same time they hold officials to be in error if the inmates exhibit nonconformity to prison rules and regulations. Similarly, prisoners may be viewed as sick persons in need of therapy, but it is also demanded that therapy should not interfere with strict surveillance and the maintenance of custodial security. These are some of the dilemmas that confront the prison administrator.

There are some correctional institutions, to be sure, that operate under very different assumptions. In a few institutions inmates are held largely responsible for their own welfare, and attempts are increasingly being made to create a prison milieu in which the expectation of inmate responsibility is the rule rather than the exception. However, these institutions and programs seem to

gain widespread public support only if there is firm assurance that more conventional methods of control will be made available for bellicose or belligerent offenders. Consequently, the more advanced methods of treatment tend to be applied chiefly to those inmates who have least need for them. In summary, it seems clear that a systematic and convincing rationale for the use of modern therapy techniques has not yet made its way very effectively into the field of correction. Conflicts between the objectives of therapy and of punitive custody are readily apparent in most penal institutions.

Official Organization.—The official organization of the prison is superimposed upon the goals and operating assumptions mentioned above. At the head of each institution is a warden or superintendent who is in most cases responsible directly to a top-level governmental official. Under the superintendent are division chiefs who manage the programs of custody, classification and treatment, business and budget affairs, industries, and medical care. A separate hierarchy of subordinate officials works under the direction of each of the division chiefs. The custodial staff, for instance, usually includes an assistant superintendent who is generally responsible for the security of the institution, a captain or two, a few lieutenants, a greater number of sergeants, and the guards or custodial officers who comprise the largest segment of the official personnel. Officers of the lowest rank have the greatest amount of contact with the prisoners. They have direct responsibility for enforcing the rules and regulations and otherwise carrying out the policies announced by the head of the institution and his administrative assistants.

Unilateral Authority.—Most prisons operate under a military-style system of authority and communication. Each officer in the staff hierarchy has specified duties and responsibilities and is linked to officers of higher and lower rank through a chain of command and a predetermined channel of communication. At each level in the hierarchy, the officers receive orders from the next higher rank and are held responsible for the performance of the officials in the next lower rank. Thus, everyday observations of inmate behaviour are reported from the lower levels of command up the ladder to the top level. Here the numerous reports are collated and official decisions are made. Then directives and supportive information flow back down the steps of the staff hierarchy from division chief to crew supervisors and to officer or guard. In the typical unilateral sequence of communication and authority, as a consequence, reports of a factual nature move upward in the chain of command, whereas administrative orders and interpretations of factual materials move down the ranks of employees.

Despite its clear logic, however, the unilateral system of authority and communication may have some serious weaknesses. This is especially true in correctional institutions where many discretionary judgments are almost inevitably made by low-ranking officers who have direct contact with the inmates, where different members of the official staff may have varied and sometimes contradictory motives and objectives, and where the society of prisoners is at odds with official policy on some crucial matters.

One problem is that many policy decisions are made by administrators who are far removed from the scene of direct and daily contact with the prisoners where the worthiness of alternative programs and policies can perhaps best be observed. Persons in high authority, dependent as they are upon the reports of lower officers, are sometimes the last to learn about the effects of their decisions. Furthermore, feedback or criticism of top-level decisions is frequently minimized. In many institutions no official procedure for such reverse flow of communication is provided. As a result, the unilateral system of communication and authority may tend to produce a considerable barrier between the officer's world of everyday experience and the picture of that world as it is seen by top-level administrators.

Administrative Communications.—The prison's administrative organization may also tend to create some questions concerning the accuracy and completeness of reports as they move up and down the ranks. For example, the judgments of administrators may be influenced by the distortions of fact likely to occur when

reports are repeatedly reviewed and evaluated as they move upward through the ranks of employees. Likewise, administrative directives are inclined to lose some of their content and effectiveness as they are passed down through the ranks. Explanations and elaborations are apt to be deleted from administrative communications as they are passed from higher to lower levels. By the time the directives reach the officers in the lowest rank they are likely to be expressed as bald and unqualified commands. As a result, administrative directives are frequently interpreted in comments and discussions that occur outside the official channels of communication. Thus, the unofficial versions of directives may determine how most officers respond to them. If this is the case, the unilateral organization of the prison, instead of eliminating the influence of hearsay and rumour, may make unofficial messages an essential part of the officer's conception of prison policy.

For many officers in the lower ranks, allegiance to administrative policies may be less important than participation in the unofficial exchange of rumours and messages within the prison community. Lower officers frequently have very little knowledge of the institution's administrative program except for the specific rules and regulations they are expected to enforce. In many cases these officers have no more influence upon the formulation of policies than do the inmates. This lack of information and influence means that officers in the lower ranks are inclined to lose interest in the official program and eventually become alienated from the administration of the institution.

Alienation and disinterest among lower officers encourage departures from administrative policies, criticisms of higher authorities, and fraternization with the inmates. The result that has repeatedly been observed is collusion between certain staff members and inmates in informal but highly standardized procedures for circumventing administrative procedures and regulations. Where such collusion occurs, the effect of prison experience is to give inmates practice in methods of deceit and nonconformity. This is one of the main reasons why prisons have often been called crime schools. It would appear that the unilateral organization that is so characteristic of penal institutions may place severe restrictions upon the possibilities of treatment and may provide an even greater barrier against prisoner rehabilitation than the bars and walls that attract such adverse comment from correctional authorities.

Inmate Organization.—Prisoner's Code.—The problems related to administrative policy are not alone responsible for the difficulties encountered in the rehabilitation of prisoners. Prisoners too, have a code of conduct, and in many instances it calls for behaviour that is directly opposed to the official rules and regulations. The prisoner's code reveals little interest in problems of prison management or programs of therapy. These prisoners agree, are the responsibility of prison officials, while the main concern of the prisoner is immediate gratification of inmate desires and objectives.

The foremost objective of most inmates is to get out of prison at the earliest possible time. The inmate who views imprisonment as a safe and pleasant substitute for civilian life is rarely found. The basic question is how to get out of prison, and a few prisoners are so intent upon escape that they are willing to assault and if necessary murder anyone who stands in their way. More of them, however, prefer less violent methods, such as digging tunnels under the walls, sawing the bars of their cells, or secreting themselves in prison vehicles that have access to the world outside. But the vast majority of prisoners confine themselves to more legitimate methods for obtaining release. Some prepare writ after writ in an attempt to find technical errors in the indictment, the trial, or the sentence that sent them to prison. Others may work hard, attend school, and participate in treatment programs in an effort to attract favourable attention. The value attached to release from prison is so great, however, that the greatest violation of the prisoner's code is to interfere with another inmate's attempt to gain freedom by any means.

Inmate Society.—Next to getting out of prison, the inmates are interested in good food, comfortable quarters, adequate clothing, a pleasant and interesting or easy work assignment, and recrea-

tion and entertainment. Comfort, variety, and individual recognition are as important in the prison community as in the world outside, and, if anything, are enhanced by the restrictions placed upon personal liberty. Most prisoners try to express their individuality by a variety of innovations in the style of their dress, their haircut, or the manner of their speech or conduct. Even more important is the fact that a considerable number of prisoners have deviant habits and unconventional desires that are by no means discouraged by the society of prisoners: the alcoholics are in constant search of intoxicants, and if whiskey cannot be smuggled into the institution, are willing to use antifreeze solution, hair dressing, and numerous other substitutes; the drug addicts make every effort to obtain narcotics; and sex deviants may use force against unwilling partners or sell themselves as male prostitutes. Strong inmates frequently intimidate weak ones, and opportunities abound in most prisons for the enterprising thief, robber, or confidence man. The mere fact of imprisonment does not discourage the inmates from trying to satisfy their illegitimate desires.

Role and Status Assignments.—The prisoner's code is designed to protect the various sub-rosa activities found in most prisons. One means of protection is the informal classification system that helps the inmates make appropriate assignments of prisoner roles and statuses. Prisoners loyal to the official administration must be prevented from becoming involved in confidential inmate activities, while those interested in illicit affairs need to be identified and guided into the social cliques and organizations where their activities are not likely to be discovered.

The process of role assignment commonly proceeds in a standardized fashion within the society of prisoners. Newly committed prisoners are first carefully questioned by inmate leaders to see if their loyalties are directed toward the officials or toward their fellow prisoners. Then the new inmate's knowledge of prisoner society and his skill in handling difficult situations are carefully examined. Finally, the new recruit is confronted by a number of contrived problems that are designed to prove his consistency, reliability, and devotion to the code of the inmates. If he passes these tests, the new inmate is tentatively accepted as a member of the prison community. Within six months or so after he arrives in prison, the new inmate's major roles and statuses are ordinarily pretty well established by his fellow prisoners. His access to different segments of prison society is regulated accordingly.

In addition to exercising great care in the assignment of roles and statuses, inmate society sets up expectations of mutual care and protection among the prisoners. Inmates engaged in any illegitimate enterprise, in order to maintain a climate favourable for its continuation, are expected to support and protect various other forbidden activities. This expectation, of course, contradicts the official rule that inmates are supposed to "do their own time" and avoid involvements with other prisoners. In any case, the expectation of reciprocal loyalties and mutual protection encourages prisoner morale and unites a large number of the prisoners in the pursuit of illicit objectives in the face of persistent staff opposition. The informal rule prohibiting any inmate from acting in a manner that might interfere with the illegitimate activities of others is the second major commandment in the prisoner's code of conduct.

The system of reciprocal loyalties among the inmates, however, is as vulnerable to important sources of outside interference as the official system of unilateral communication and authority. Deviations from the system are as much the rule as the exception. One problem is that inmates striving for power and higher status within the society of prisoners are frequently willing to violate the code. Again, the system is far more vulnerable than the prisoners would care to admit. Officials have easy access to inmate informers who divulge privileged information in return for various rewards that can be granted by the administration. In these cases the secrecy of the reciprocities system actually serves to protect the informers. Finally, many of the inmates are antagonistic toward the society of prisoners. They feel an allegiance to the officials and wish to take their punishment so that they can return promptly to civilian life. All of these factors

ments. The prisoner became an important figure in the Korean war, the object of greater attention by the combatants than in either World War I or II. It appeared that a change in the status of the POW might be taking place with the prisoner being considered still a combatant and the prison compounds mere extensions of the fighting areas. If this apparent trend were to continue it would seriously threaten the improved conditions of prisoners afforded by the Geneva conventions.

Evidence of that trend was seen in the Vietnam war. Vietnamese prisoners of both the Vietcong and South Vietnam tended to receive treatment as political subversives rather than as prisoners of war, both sides taking the stand that war had not been declared. When North Vietnam announced in July 1965 its intention to try as "war criminals" U.S. flyers who had been downed over its territory, public protests followed in the U.S. and in other countries, and from many sources, including those who had been critical of the U.S. bombing of North Vietnam.

U.S. POW Code of Conduct.—Upon return of the surviving U.S. prisoners from Korea—about 4,428 men—the U.S. government undertook a formal study of POW problems, appointing a special committee of military and civilian leaders to consider all aspects of the subject. Some of the specific problems considered were the causes of the apparent defections to the enemy by a few U.S. servicemen, the truth about the so-called brain washing, the propriety of punishing returned POWs for collaboration with the enemy under duress, and the existence or creation of a uniform standard of conduct for servicemen in battle and in captivity.

The report of the committee, made public in July 1955, found proper the action of U.S. authorities in bringing some 14 servicemen to trial by courts-martial for their acts of misconduct while in a prison camp. Brain washing was found to have had little lasting effect upon the prisoners in Korea. To guide U.S. servicemen who might be taken prisoner, the committee presented the following code of conduct which the president of the United States directed all servicemen to follow:

I

I am an American fighting man. I serve in the forces which guard my country and our way of life. I am prepared to give my life in their defense.

II

I will never surrender of my own free will. If in command I will never surrender my men while they still have the means to resist.

III

If I am captured I will continue to resist by all means available. I will make every effort to escape and aid others to escape. I will accept neither parole nor special favors from the enemy.

IV

If I become a prisoner of war, I will keep faith with my fellow prisoners. I will give no information or take part in any action which might be harmful to my comrades. If I am senior, I will take command. If not, I will obey the lawful orders of those appointed over me and will back them up in every way.

V

When questioned, should I become a prisoner of war, I am bound to give only name, rank, service number and date of birth. I will evade answering further questions to the utmost of my ability. I will make no oral or written statements disloyal to my country and its allies or harmful to their cause.

VI

I will never forget that I am an American fighting man, responsible for my actions, and dedicated to the principles which made my country free. I will trust in my God and in the United States of America.

PRISTINA, a town and the administrative centre of the Kosovo-Metohija autonomous region of the Socialist Republic of Serbia, Yugos., lies 97 km. (60 mi.) NNW of Skopje on the road to

Kraljevo. Pop. (1961) 38,593. New buildings have changed but not obliterated the Oriental appearance of the town. Pristina is situated in the Kosovo Plain, the "Field of Blackbirds" where the Serbian Empire was destroyed by the Turks in 1389. The region has many medieval monuments. Agriculture and minor industries form the main occupations. In the neighbourhood there are lead, zinc, and silver mines. Pristina was liberated by the Serbs from the Turks in 1912; during World War II it was occupied by the Germans. (V. DE.)

PRITCHARD, CHARLES (1808–1893), British clergyman and astronomer who was among the first to apply photography to the determination of stellar parallax, was born at Alberbury, Shropshire, on Feb. 29, 1808. He was educated at St. John's College, Cambridge, elected a fellow of his college in 1832, was ordained in 1834, and became a schoolmaster. After his retirement in 1862, he was able to devote himself to his interest in astronomy, and was elected president of the Royal Astronomical Society in 1866. In 1870 he was elected Savilian professor of astronomy at Oxford and founded the new university observatory. In 1881 he commenced a systematic study of stellar photometry and measured the relative brightness of 2,784 stars between the north celestial pole and about -10° declination; the results were published in 1885 in his *Uranometria Nova Oxoniensis*, for which he was awarded, conjointly with E. C. Pickering, the Royal Astronomical Society's gold medal (1886). Between 1888 and 1892 he made a systematic measurement of the parallax of second-magnitude stars.

Throughout his life, Pritchard regretted being without a pastoral cure. Many of his frequent religious addresses to learned bodies, some of them concerning the harmony between science and Scripture, were published. Pritchard died on May 28, 1893. (O. J. E.)

PRITHVI NARAYAN SHAH (1730–1775), king of Gurkha from 1742 to 1775, was one of the founders of modern Nepal (q.v.). His Rajput ancestors, driven from Udaipur by Muslim invaders, had set up little kingdoms in the Himalayas. Prithvi Narayan succeeded to the throne of one of these kingdoms, Gurkha, in 1742, soon after his father had been driven from Nawakot which he had captured from the Malla king of Katmandu. Under Prithvi Narayan the Gurkhas resumed the war against the Malla kingdoms of Katmandu, Patan, and Bhadgaon and advanced as far as Kirtipur where they were defeated. Prithvi Narayan however was a man of ruthless determination and ability and, unable to subdue the three kingdoms by direct assault, he blockaded the valley of Nepal for several years. Eventually, in 1768, aided by the intrigues of the three Malla kings, he succeeded in conquering all three kingdoms. He then moved his capital from Gurkha to Katmandu and proceeded to reduce the principalities of the Chaudhis Raj in the west and to persuade the Kirant tribes of the east to accept his overlordship. Prithvi Narayan died in 1775 and his eldest son who succeeded him only survived him by three years. When his infant grandson succeeded to the throne Prithvi Narayan's younger son, Bahadur Shah, who acted as regent, greatly extended his father's conquests. (R. R. P.)

PRIVATEER, an armed vessel belonging to a private owner and commissioned by a belligerent state to carry on operations of war or reprisals. Since the crew was not paid by the state, privateers were entitled to cruise for their own profit, deductions from the value of prizes taken being made by the admiralty courts in England or their equivalents as prize courts elsewhere, at which all captures had to be condemned as legitimate under the prize laws. This method of commerce destruction was adopted by all nations from the earliest times until the 19th century, but it frequently proved impossible to restrain the activities of privateers within the legitimate bounds laid down in their commissions or letters of marque. Hence in earlier times it was often difficult to distinguish between privateers, pirates, corsairs, or buccanniers, many of whom sailed without genuine commissions. (See BUCCANNERS; PIRACY.)

Before regular navies were established, the state relied on the assistance of private ships equipped for war such as, for example, those from the Cinque Ports in England. The earliest mention of

letters of marque issued to English ships is in a patent roll of Edward I dated 1293 which ordered a stay of letters of marque previously granted to his subjects in Aquitaine. In the 14th century admiralty courts were instituted in England to administer prize law, and at the beginning of the 15th century the High Court of Admiralty was established. Local vice-admiralty courts were later set up, the earliest being at Jamaica in 1662. Throughout the Tudor period privateers such as Sir Martin Frobisher, Sir Richard Hawkins, and Sir Francis Drake were encouraged or restrained according to prevailing political conditions. At the same period the Dutch Sea Beggars and French Huguenot privateers were active.

This state of affairs continued throughout the next century, English buccaneers in the West Indies such as Sir Henry Morgan or William Dampier sometimes sailing as genuine privateers and sometimes not. From 1690 French privateers from Dunkerque and Saint-Malo were particularly active against English commerce. With the growth of a regular navy the British Admiralty began to discourage privateering, because it was more popular among sailors than serving in the navy, and because it often led to trouble with neutrals, though a declaratory act was always passed at the beginning of a war, laying down the right to capture enemy vessels at sea and to have such captures adjudicated under prize law. Extensive use of privateers was made in France and in New England throughout the 18th century. During the American Revolution the American colonists found it difficult to form a new navy because over 1,000 privateers were licensed. The popularity of privateering continued in the War of 1812 between Great Britain and the United States when, for example, the brig "Yankee" alone seized or destroyed \$5,000,000 worth of English property. Meanwhile, the prospects of French privateers had been ruined by the efficiency of frigates and convoy escorts.

Privateering was abolished in 1856 by the Declaration of Paris (q.v.), though the United States refused to accede on the grounds that privateering made it possible to economize on the cost of a navy. During the American Civil War the president was authorized to commission privateers, but both sides preferred to arm their own merchantmen as regular warships. The rise of the American navy at the end of the century, and the realization that privateering belonged to an earlier form of warfare, disposed the United States to recognize the necessity of abolishing it. At the Second Hague Conference in 1907 several conventions on naval warfare in respect to merchant vessels at sea were adopted, but the one netting up an international prize court to hear appeals from belligerent prize courts was never ratified. It was then stipulated, and has since become part of international law, that armed merchant ships must be listed as warships, though there have been various interpretations of the word "armed." The ambiguous status of the privateer has ceased to exist, since under the seventh Hague convention the state now assumes full responsibility for all converted ships engaged in military operations; but the right to arm merchant vessels in self-defense was generally admitted in World Wars I and II.

Malo, *Les Derniers Corsaires, Dunkerque, 1715-1815* (1925); C. J. Colombos, *The International Law of the Sea*, 5th ed. (1962). (C. C. L.)

PRIVET, any shrub of the genus *Ligustrum*, belonging to the olive family (Oleaceae), and containing about 50 species, natives of temperate and tropical regions of the old world; only the common privet (*Ligustrum vulgare*) is a native of Europe and northern Africa. Privets have evergreen or nearly evergreen opposite entire leaves, and dense clusters of small, white, tubular four-parted flowers, followed by small, globular, usually black fruits. The best-known species is the common European privet, which makes good hedges; there are numerous varieties with variegated leaves. The California privet (*L. ovalifolium*), half-evergreen and native to Japan, is a commonly grown hedge. The wax privet (*L. japonicum*), and *L. lucidum* and *L. massalongianum* are fine evergreen species, hardy in warm regions. Mock privet (*Phillyrea*), a member of the same family, is an ornamental evergreen shrub from the Mediterranean region, hardy in warm places. (N. Tr.)

PRIVILEGE, in Anglo-American law, has at least two meanings: the first is that of an exceptional power, immunity, or advantage enjoyed by a person or class; the second, in the United States, is analogous to a constitutional right.

Privilege from arrest exempts certain persons from arrest in civil proceedings and, in some cases, on criminal charges. This form of privilege may be permanent, as in the case of a foreign minister and his suite, who may not legally be arrested in any circumstance, or temporary, as in the case of witnesses while a suit is being tried.

Privileged communications are those between persons who have a special duty of fidelity and secrecy toward each other, such as husband and wife. Communications between attorney and client are privileged when made in connection with prospective litigation. The law will not allow such communications to be divulged or inquired into in judicial proceedings without the consent of the person who made them. In a few states of the U.S. this privilege has been extended by statute to other communications, such as those between doctors and patients or confessions to priests. Statements and publications, which otherwise would be libelous or slanderous, may be privileged; this means that a person can make or publish them with immunity if he does so while performing certain political, judicial, social, or personal duties. If absolute, the privilege applies regardless of the speaker's motives or the falsity of his statement, as in the case of statements made in legislative debates. Conditional privilege gives immunity unless the speaker's actual malice and his knowledge of falsity are shown. (See **PARLIAMENT: The Two Houses of Parliament**; **DEFAMATION**.)

In most countries certain debts are privileged—that is, such debts as funeral expenses or servants' wages must be paid by the executor or trustee in bankruptcy in preference to other debts.

By Art. IV sec. 2 of the United States Constitution, "The Citizens of each State shall be entitled to all Privileges and Immunities of Citizens in the several States." The U.S. Supreme Court has interpreted this as forbidding discrimination by any state against citizens of other states in favour of its own. Discrimination against nonresidents is an infringement, but not reasonable differences of treatment between residents and nonresidents. Thus a state may require residence within its borders for a given time before a person previously a resident of another state may vote; also, discrimination against nonresidents may be reasonable because of considerations of public health, safety, or welfare. Nonresidents, however, must be given access to state courts upon terms that are reasonable and adequate for enforcing their rights, if the terms differ from those for residents. In the exercise of its taxing powers a state may not substantially discriminate between residents and nonresidents, but the test for such an absence of discrimination involves considering the entire state tax system to determine its overall fairness.

The 14th Amendment to the Constitution (sec. 1) provides that "no State shall make or enforce any law which shall abridge the privileges or immunities of citizens of the United States." With regard to this provision, the Supreme Court in 1873 repudiated the idea that, when the amendment was adopted in 1868, it converted the rights of the citizens of each state into privileges and immunities of United States citizenship. The court thereby largely nullified the clause, which had been intended to guarantee the right to vote to Negroes in the South; the court held that the only privileges protected by the amendment were those which owed their existence to the "Federal Government, its National Character, its Constitution, or its laws." (*The Slaughter-House Cases*, 83 U.S. 36, 79.) These privileges existed prior to this amendment and were already protected against state interference under the principle of federal supremacy.

It is a federal crime to conspire to injure, oppress, threaten, or intimidate any citizen in the free exercise and enjoyment of any privilege secured by the Constitution, or under colour of law willfully to deprive any inhabitant of a state of any such privileges or immunities. Civil damage actions may also be brought for deprivation (or a conspiracy for deprivation) of these privileges.

The privilege against self-incrimination is embodied in the Fifth Amendment to the Constitution and in most state constitutions.

It forbids compelling any person to be a witness against himself; and it extends to a witness in any type of governmental proceeding when the answer to a question he is legally required to answer might be used against him (but not against others) in a future criminal proceeding by that government.

See IMMUNITY; see also references under "Privilege" in the Index.

PRIVY COUNCIL, theoretically the British sovereign's private council, as distinct from the medieval great council, or council of magnates, and from council in parliament, now called parliament. It ceased to be an active body because (1) it lost most of its judicial functions; (2) the sovereign preferred to use informal meetings of ministers in cabinet; and (3) the sovereign ceased to take responsibility for political decisions. Meetings are held from time to time for the taking of formal decisions (e.g., the making of orders in council), but usually only the quorum of three lords of the council are present and there is no discussion.

There is, however, a privy council office, with the lord president of the council as responsible minister. It is concerned with the making of orders in council and with a wide variety of functions deriving mainly from the power of the sovereign in council to issue royal charters, now used chiefly by municipal corporations and by charitable bodies engaged in education, research, the encouragement of literature, science, art, etc. Among the bodies with which it is concerned are the universities, various research councils (e.g., the agricultural research council, the medical research council and the research council of the department of scientific and industrial research) and the bodies concerned with the maintenance of professional standards (e.g., the general medical council). It bears the main responsibility for scientific research through the department of scientific and industrial research. Usually the privy council functions through committees, some standing and some *ad hoc*. The most famous of its committees is, however, statutory, the judicial committee of the privy council, which hears appeals from ecclesiastical courts, prize courts and courts from all colonies and some independent countries of the commonwealth (see PRIVY COUNCIL, JUDICIAL COMMITTEE OF).

History of the Privy Council.—The privy council, like all the British institutions of central government, is descended from the court of the Norman kings. This *curia regis*, composed of the king's tenants in chief, his household officials and anyone else whom the king chose to summon, performed all the functions of central government. According to feudal theory, tenants owed suit to their lord's court; but every great lord had also his household officials to transact his daily business. The *curia regis* expanded or contracted according to the nature of the business under consideration. The ordinary routine would be carried out by the officials, assisted by such barons as happened to be at court; for more important business the king would secure the attendance of a greater number of his tenants in chief; and on really vital matters the household officials would tend to become a numerically insignificant technical element in a large feudal assembly.

As time went by the larger and smaller gatherings came to be distinguished adjectivally; later, these adjectives developed a technical significance, until, although still remaining for a time merely different manifestations of a one and indivisible body, the larger assembly developed into the great council and the parliament, the smaller into the king's council. In early days the presence of many barons at conciliar meetings was the mark of a strong king; later, as the barons came to realize that attendance was not merely a tiresome incident of feudal tenure but a source of political power, that obligation became a privilege. Thus, in the later middle ages there developed a struggle between king and greater barons for the control of the king's council. In the end the barons failed to secure their greater demands—exclusive membership and the control of appointment and dismissal—because, though anxious to control and willing to be appointed, they could never be relied upon for constant attendance. Further, with the passing of the feudal organization of

society, baronial counsel ceased to be expert advice on matters of government.

By the time of Henry VII this council had become the instrument of the crown. It was composed of an inner ring of counselors proper, who took an oath and sat at the council board, and of an outer ring of technical experts and dignitaries. Though they might occasionally be called upon for advice, the latter were not members of the board, did not take the conciliar oath, but merely that of their respective offices, and performed the technical and routine work of the central and provincial courts of the council. It was the policy of the Tudors to rule the country paternally by the prerogative exercised through the medium of the council.

This conception of government necessitated precision, subdivision and specialization, and thus the king's council and its functions were divided among the privy council, the courts of Star Chamber, of requests and of high commission (*q.q.v.*), and such local offshoots as the courts and councils of the north, and of Wales and the Marches. A distinction between the council with the king and the council at Westminster had appeared from time to time during the middle ages. It now became "sharper and more permanent." The body following the king was commonly known as the council at court, while the other continued to be called the king's council in the Star Chamber. The former body became the privy council.

This conciliar government was admirably suited to a period of transition. But the need of this somewhat arbitrary, if paternal, government had passed with the Tudors. Moreover, this small but all-powerful bureaucracy depended for its efficiency on a resolute and discriminating sovereign, capable of choosing the right men and of superintending their labours. The Stuarts did not possess these qualifications. The house of commons, hitherto accustomed to follow the leadership of privy councilors, had now, with increased experience of partnership in government, developed a mind and policy of its own. Of the judicial aspect of the council's activities the common lawyers were coming to show an even more threatening jealousy, a jealousy justified by the misguided action of the Stuarts in checking the natural evolution of these courts toward independence of executive control and in using them to enforce, not justice, but policy. No wonder, then, that as religious and constitutional controversies developed between crown and parliament the attention of malcontents became focused on conciliar jurisdiction, nor that, when the parliamentary cause at last triumphed in 1641, the whole system of conciliar government was swept away. Only the privy council was spared. It was never legally abolished. It perished in the interregnum (though the name was resuscitated in 1657) and was restored with the return of Charles II in 1660.

Both in the middle ages and for several centuries later contemporary opinion favoured 20 as about the ideal total of conciliar membership. But seldom did practice conform with theory. When the privy council register begins, in 1540, we do, indeed, find 20 members, but by Henry VIII's death there were 29. In Edward VI's reign the record was 40, in Mary's 44, and, although Elizabeth I reduced the numbers to between 12 and 20, the Stuarts, as usual, were less successful. By 1623 the total had increased to 35, and Charles I's council averaged about the same figure. At the Restoration the problem of numbers became even more acute. Charles II managed to begin with only 28, but the total had reached 47 by 1679. Sir William Temple's abortive attempt at conciliar reform temporarily reduced the figure to 33, but by 1685 it was back again at 48, by 1707 it had reached 60 and, by 1723, 65. In practice, however, Charles II and all later monarchs preferred to have matters of policy discussed privately by their principal advisers in cabinet.

The last serious attempt to restore the privy council to its former influence may be found in the clause of the Act of Settlement (1701), which enacted that, on the Hanoverian accession, "all matters and things relating to the well-governing of the kingdom, which are properly cognizable in the privy council by the laws and customs of this realm, shall be transacted there, and all resolutions taken thereupon shall be signed by such of the privy council as shall advise and consent to the same." But the pro-

posal was by that date impracticable, and the clause was repealed in 1705 before it even came into force. The council board had been not merely short-circuited by the cabinet, it had even lost the power of debating such measures as came before it. In 1711 a debate on the subject in parliament elicited the remark that "the privy counsellors were such as were thought to know everything and knew nothing. Those of the cabinet council thought nobody knew anything but themselves." And the last occasion on which the council asserted its former rights was when, in 1714, as Queen Anne lay dying, certain Whig lords forced their way in at a meeting of the lords of the committee (see *CABINET*), claimed their right to be present as counselors of the crown, converted the meeting into a session of the privy council and, reinforced by their conciliar colleagues, ushered in the Hanoverian succession. From the accession of George I the privy council may be described as a purely formal body meeting on purely formal occasions to transact purely formal business. By 1960, there were more than 300 "right honourable lords and others of Her Majesty's Most Honourable Privy Council." They were mostly dignitaries who had held, or held, high political, judicial or ecclesiastical office, though the list occasionally included eminent persons in science or letters. Office lasts for the life of the sovereign and six months after, but a new sovereign may renew the appointment. See also references under "Privy Council" in the Index.

PRIVY COUNCIL, JUDICIAL COMMITTEE OF, a British tribunal composed of certain privy councilors which on petition hears various appeals from the United Kingdom, from British crown colonies, and from those independent members of the Commonwealth which have not abolished this final appeal from their courts.

The tribunal's authority derives from the Judicial Committee Act (1833), but its origins lie deep in English history. From the earliest times the king has been accounted the supreme source of justice and his council has always had judicial as well as advisory functions. In the later Middle Ages, when courts for all ordinary causes were well established, a reserve of residual justice remained with the king and extraordinary justice was done by the king's council. For this purpose councilors worked in committees, which were the origin of some of the prerogative courts (*q.v.*). These courts, which came into disrepute under the Stuarts, had all been abolished or had fallen into disuse by 1689. From that time until 1833, appeals to the sovereign, or to the sovereign in council, especially from overseas, were dealt with by a general committee of the Privy Council. In 1833 the Judicial Committee Act created a special judicial tribunal. The rules then laid down with regard to the composition and procedure of the committee and the nature of its jurisdiction continue, with modifications, to determine the committee's form and actions.

The members of the committee are the president of the Privy Council, former presidents of the Privy Council, the lord chancellor, the lords of appeal in ordinary, and any other privy councilors who have in the past held such office. Other members are judges of the Supreme Court of England and Northern Ireland, of the Court of Session in Scotland, and also (by the Judicial Committee Amendment Act, 1895), provided they are privy councilors, judges or former judges of the superior courts of British colonies or of independent Commonwealth countries. The committee sits in the council chamber in Whitehall, where it hears petitions formally addressed to Her Majesty in Council. A quorum of three members is needed for every case, and members cannot attend a hearing unless summoned. The committee can sit in divisions and hear various cases simultaneously. It is in no way bound by previous decisions, and its judgment is made in the form of a report to the sovereign, allowing or disallowing the appeal. Dissenting opinion

is not disclosed. The decision may then be implemented by means of an order in council.

Among the independent members of the Commonwealth from whose courts appeal to the judicial committee still lies are Australia, New Zealand, Ceylon, Trinidad and Tobago, Jamaica, and Sierra Leone. Appeals also lie from Jersey, Guernsey, and the Isle of Man. In the case of Malaysia the committee reports not to the queen but to the head of the Federation of Malaysia.

The 1833 act gave to the sovereign the power to refer any question whatsoever to the committee, and such "special references" are still made. One such case was that of the Rev. Godfrey Mac-Manaway, who at the general election of Feb. 1950 was returned to Parliament as member for West Belfast. The judicial committee decided that as an ordained clergyman of the Church of Ireland he was disqualified from sitting in Parliament. Appeals concerning the union of benefices are also referred to the committee under this section of the act. By acts of Parliament passed in 1956 and 1958, doctors, dentists and opticians may appeal to the committee against the erasure of their names from the registers of their respective professions.

PRIVY PURSE, the amount set apart in the civil list (*q.v.*) for the private and personal use of the sovereign in England. During the reign of Queen Victoria it was £60,000 a year, but on the accession of Edward VII the amount was raised to £110,000, the sum also received by George V and George VI. King Edward VIII was granted £77,000 a year, until he should marry. At the accession of Queen Elizabeth II in 1952 the amount was fixed at £60,000 a year. Under Victoria the household offices of keeper of the privy purse and private secretary were combined.

PRIZE, in law, may be defined as a vessel, aircraft, or goods, acquired through capture by a belligerent state, which is subject to condemnation by a Prize Court (*q.v.*).

Judicial Inquiry.—"Capture" and "prize" are not synonymous terms, and a legal determination that the captured property is good prize, within the accepted definition, is necessary before the captor may exercise any beneficial rights in it. A decree of condemnation declares the prize to be the property of the capturing sovereign and may be accompanied by an order for sale, purchase under which gives an internationally valid title. In the 18th century title to a prize sometimes changed simply by virtue of the capture, but by the modern usage of nations a judicial inquiry must pass upon the case. Within certain undefined limits the nature of the legal process and the definition of condemnable vessels and goods are left by international law to national choice.

Property Subject to Condemnation.—Enemy vessels, enemy goods in enemy or in neutral vessels, neutral goods which are contraband, and neutral vessels which have been captured in the act of running a legal blockade or rendering unneutral service are subject to condemnation. Enemy warships or other public ships are liable to condemnation, but they are seldom the subjects of actual adjudications. During a war enemy states do not appear as claimants before the Prize Court, and after a war rights and liabilities resulting from captures are usually settled as part of the general peace settlement. The enemy character of vessels and goods is determined by the nationality or the domicile of the owner, and evidence both intrinsic and extrinsic to the vessels and its papers may be introduced. Aircraft have been added, by statute, to the subjects of prize law (see U.S., act of June 24, 1941, 55 Stat. 261, and U.K., Prize Act, 1939, s. 1 [1], 2 and 3 Geo. VI, c. 65). These statutes provide for the application of the law of prize even when the aircraft is captured on or over land. For England the term "vessels" includes merchantmen, lighters, rafts, tugs, boats, and all other naval craft together with their appointments. For the United States, however, nonseagoing vessels, such as barges propelled by sweeps or by poling, and boats having no means of propulsion are not regarded as maritime prize.

Maritime Capture.—Only "maritime capture" is subject to condemnation under the law of prize. Traditionally, "maritime capture" includes capture by naval forces upon the high seas or in rivers, ports, and harbours. The French Prize Court has held that captures upon inland waters are not liable to condemnation as maritime prize. In Italy prize extends to captures on inland waters; and the German Prize Court Law of 1939 covered captures on land and sea.

Prize Money.—Individuals having some connection with the capture of a prize may share in its value only if the captor state so provides. In the past, prize money or "bounty" has been paid, partly as a reward for bravery and as a stimulus to exertion and partly as a compensation for the poor rates of pay prevailing in naval services. However, prize bounty was abolished in the United States in 1899 (30 Stat. 1007, sec. 13) and in England in 1948 (Prize Act of 1948, 12 and 13 Geo. VI, c. 9).

BIBLIOGRAPHY.—C. J. Colombos, *A Treatise on the Law of Prize*, 3rd ed. (1949); J. W. Garner, *Prize Law During the World War* (1927). (F. T. v. B.)

PRIZE COURTS AND PRIZE LAW, in naval warfare, are instrumentalities by which the legality of captures of ships and goods at sea and related questions are determined. The establishment of such courts is both a right and duty of belligerents. In a 1916 British case, Lord Parker observed that: "but for the existence of Prize Courts no one aggrieved by the acts of a belligerent power in times of war could obtain redress otherwise than through diplomatic channels and at the risk of disturbing international amity. An appropriate remedy is, however, provided by the fact that according to international law, every belligerent power must appoint and submit to the jurisdiction of a Prize Court to which any person aggrieved by its acts has access, and which administers international as opposed to municipal law—a law which is theoretically the same, whether the court which administers it is constituted under the municipal law of the belligerent power or of the sovereign of the person aggrieved, and is equally binding on both parties to the litigation" (*The Zamora*, 1916, 2 A.C. 77).

The judgment of a prize court is binding upon the parties to proceedings before it, that is, normally the captor and the individual or corporation, neutral or enemy, that challenges the validity of the capture. It is not necessarily binding, however, on the state whose national is involved, whether or not it is binding being dependent upon the conformity of the judgment with international law. In case of inconsistency the state of the captor becomes responsible to the state of the claimant, individual or corporation. As the U.S. commissioner William Pinkney pointed out before the Anglo-American mixed commission, established pursuant to the Jay treaty of Nov. 19, 1794, to determine the legality of the seizure of the American ship "Betsey" by the British captor:

A belligerent has this jurisdiction for its own safety—because it is answerable to other nations for the conduct of its captors. It is allowed exclusive cognizance of the capture for the purpose of ascertaining whether it will confirm it and thus complete its own responsibility, or give to the claimant adequate redress against the captor and thus exonerate itself. . . . The judgment of its prize court in the last resort, in general, perfects or destroys that liability. If it grants adequate redress there is nothing to be answerable for, but if instead of doing so it completes the original injury by rendering it irreparable by any ordinary means, the national responsibility is obviously perfect. The injury becomes its own, and the neutral, from being compelled to ask redress against the captor is now authorized to ask it against his nation. . . .

Claims of belligerents against each other arising from capture are usually settled by the peace treaty. Claims of neutrals against belligerents are settled through diplomatic negotiations or, rarely, international arbitral tribunals. At the second Hague peace conference a proposal was adopted to establish an international prize court to settle disputes between neutrals and belligerents (see below).

As the objective of war at sea became increasingly the denial to the enemy of all trade, so prize courts and prize law and particularly the latter were gradually adapted to serve this end. Economic warfare became one of the most significant developments in World Wars I and II. This fact was shown in the ex-

panding and eventually all-embracing concepts of contraband and blockade and the increasing severity of measures taken by belligerents, not merely against enemy, but also against neutral vessels, which came to be regarded by prize courts as permissible.

Prize Courts.—Prize courts are municipal (internal) courts and their character and organization are determined by national tradition and law. It is possible to distinguish two categories: judicial and administrative. English and United States prize courts are purely judicial but the prize courts of other nations are either purely administrative or of a mixed character.

In England, jurisdiction in matters of prize was vested from the 14th century by royal proclamations or commissions in the admiral's court along with jurisdiction over ordinary maritime cases such as collision or salvage. Statutory prize jurisdiction was conferred on the high court of admiralty by the Naval Prize act of 1864 which continued in the second half of the 20th century to be the basic law. It was amended in 1894, 1914, 1918 and 1939. By the High Court of Judicature act of 1891 and the Supreme Court of Judicature (Consolidation) act of 1925 jurisdiction in prize cases was transferred to the high court of justice and exercised by its probate, divorce and admiralty division. The practice continues, though not considered essential since 1864, to issue a royal commission at the beginning of war concerning exercise of jurisdiction in prize cases. Since 1864 appeals have been taken, in prize cases, to the judicial committee of the privy council, whose determinations are final, and in all other cases, to the court of appeal and ultimately the house of lords. The Prize act of 1939 was applicable in the United Kingdom, in the British dominions (but not in Canada and the Union of South Africa), in British protectorates, colonies and territories held under mandate from the League of Nations and in other territories in which the British crown had prize jurisdiction. In these territories prize jurisdiction was conferred upon the appropriate ordinary courts. The act of 1939 applied to ships as well as aircraft.

In the United States, the constitution (art. iii) provides that the jurisdiction of the United States shall extend "to all Cases of admiralty and maritime Jurisdiction." The judicial code (24, par. 3) provides that federal district courts shall have original jurisdiction "of all prizes brought into the United States; and of all proceedings for the condemnation of property taken as prize" (28 U.S.C.A. 41 [3]). Appeals from their decrees in prize cases go directly to the supreme court (Judicial Code 238, 28 U.S.C.A. 345). Bounty and prize moneys were abolished by the act of March 3, 1899, which declared that "all provisions of the law authorizing the distribution among captors of the whole or any portion of the proceeds of, or providing for the payment of bounty for the sinking or destruction of vessels of enemy hereafter occurring in war, are hereby repealed" (30 Stat. 1044, sec. 13). In Britain, the Prize act of 1948 abolished prize money. In France, jurisdiction was exercised by an administrative tribunal composed of a member of the council of state (*conseil d'état*), the highest administrative tribunal in France, six members chosen from the *maîtres des requêtes*, and officials of the ministries of foreign affairs and marine. The *conseil d'état* itself exercised appellate jurisdiction in prize cases. In Belgium prize courts were of a mixed character being composed partly of judges from the court of appeal of whom two were appointed, and four representatives of the navy and commerce. Appeals lie to the regular court of appeal. During World War II no prize court was established in Belgium. In Italy prize courts were partly judicial and partly administrative in composition; limited appeal was permitted to the court of cassation, the highest judicial authority. In Germany the prize courts of both original and appeals jurisdiction were of mixed character, and Chinese and Japanese prize courts followed the same pattern. No prize court was established in the U.S.S.R. during World War II. The difference in the character of prize courts in various countries does not necessarily mean that these countries do not administer justice, but in the fact that whereas in the United States and England prize jurisdiction is exercised by existing ordinary courts, in other countries it is the business of *ad hoc* tribunals.

Prize Law.—The law applied by prize courts is international law, customary and conventional. In England, the United States and other common-law countries the rule prevails that international law is part of the law of the land: "International law is part of our law, and must be ascertained and administered by the courts of justice of appropriate jurisdiction, as often as questions of right depending upon it are duly presented for their determination. For this purpose, where there is no treaty, and no controlling executive or legislative act or judicial decision, resort must be had to the customs and usages of civilized nations" (Justice Horace Gray, *The Paquete Habana*, 1900, 175 U.S. 677). Lord Parker said: "... the law which the Prize Court is to administer is not the national law or, as it sometimes is called, the municipal law, but the law of nations—in other words, international law" (*The Zamora*, 1916, 2 A.C. 77). Similarly Chief Justice John Marshall declared: "The law of nations is the great source from which we derive those rules, respecting belligerent and neutral rights, which are recognized by all civilized and commercial states throughout Europe and America" (*Thirty Hogsheads of Sugar v. Boyle*, 1815, 9 Cranch 191).

There is a practice of long standing for belligerents, at the outbreak of war, to enact prize law through statutory legislation dealing with both substantive and procedural rules. Thus England promulgated prize court rules in 1939; France the decrees of Sept. 2, 1939, amplified by numerous instructions; Germany the Prize Court law of Aug. 28, 1939, amended on Dec. 13, 1940; and Canada the Prize act of 1945. In the United States, congress enacted the Prize act of June 24, 1941 (55 Stat. 261), extending prize jurisdiction to aircraft. Such enactments are presumed to be declaratory of international law but they are in any event binding upon the courts. "It cannot, of course, be disputed that a prize court, like any other court, is bound by the legislative enactments of its own sovereign state. . . . But it is none the less true that if the . . . legislature passed an act the provisions of which were inconsistent with the law of nations, the prize court in giving effect to such provisions would no longer be administering international law" (Lord Parker, *The Zamora*, 1916, 2 A.C. 77). The same would be true in the United States as indicated by Justice Gray in the *Paquete Habana* (case 9), and in other countries. The difference between the Anglo-American and continental courts is that the latter do not feel free even to examine the consistency between international and municipal law since they are bound to apply the latter in any event. A difference arises in respect of British orders in council and equivalent decrees in other countries. Such orders in council are not binding upon the courts unless based upon statutes for the king in council cannot change the law administered by the courts in England any more than he can prescribe the law to be administered by prize courts. However, the prize court will apply orders in council when "they amount to a mitigation of the crown rights in favour of the enemy or neutral, as the case may be" (Lord Parker, *The Zamora*, 1916, 2 A.C. 77). Equivalent decrees would be given effect in other countries. No problem arises in connection with conventional law as this is applicable in most countries in accordance with national law. In the evolution of prize law in England and the United States precedents played a decisive role as they did in the formation of common law. Precedents do not have a comparable authority on the continent although a court would not easily depart from or overrule them.

With a view to ensuring greater uniformity in the application of law by prize courts, two methods were tried: on the one hand, the adoption of agreed rules by treaties or conventions and on the other the establishment of an international prize court. The most important among the former are: the declaration of Paris, 1856; some of the Hague conventions of 1899 and 1907 (namely the 6th convention relative to the status of enemy ships at outbreak of war, the 7th relative to the conversion of merchant ships into warships, the 11th relative to certain restrictions on the exercise of the right of capture in maritime war, and the 13th relative to the rights and duties of neutral powers in maritime war); the London declaration of 1909; and the London protocol of 1936 regarding action by submarines against merchant ships. The bind-

ing force of the Hague conventions was dubious because it depended to some extent on their having been ratified by all belligerents which was not usually the case. The conventions were, however, applied, in principle, by British prize courts in both World Wars I and II. The London declaration never entered into force but its rules were applied to the extent that they were deemed to be declaratory of customary international law. The London protocol of 1936 was largely disregarded in World War II by the major belligerents. This, at any rate, was the opinion of the Nürnberg International Military tribunal for the trial of major German war criminals:

In view of all the facts proved and in particular of an order of the British admiralty announced on May 8, 1940, according to which all vessels should be sunk at sight in the Skagerrak, and the answers to interrogatories by Adm. Chester W. Nimitz stating that unrestricted submarine warfare was carried on in the Pacific ocean by the United States from the first day that nation entered the war, the sentence on Adm. Karl Dönitz is not assessed on the ground of his breaches of the international law of submarine warfare. (Judgment of Oct. 1, 1946. International Military Tribunal, *Trial of the Major War Criminals*, *Official Documents*, vol. i, p. 313 [1947].)

To ensure greater uniformity in the jurisprudence of prize courts the establishment of an international prize court with jurisdiction on appeals from national prize courts was envisaged at the second Hague conference in 1907. As noted above, judgments of national prize courts, in case of inconsistency with international law, engage the responsibility of the captor states. To provide a judicial method for settling disputes between states in such cases, an international tribunal would be obviously useful. It was also realized that in spite of their professions national prize courts apply international law as interpreted by their governments and they are bound by municipal statutes. However, the Hague convention of 1907 for an international prize court was never ratified.

Task of Prize Courts.—According to the principle "all prizes must be judged," the main question for prize courts is: "prize or no prize." In the past, prize courts, particularly in England and the United States, were also concerned with awarding prize and bounty moneys and allocation of shares between the crown and the admiralty, the so-called *droits* of the crown and the *droits* of admiralty. Judgments of prize courts condemning ships or cargoes or both provide a title for the captor which is "good against the world," without prejudice, of course, to the right of the injured state to seek a remedy in accordance with international law. As noted, prize courts were from a functional point of view instruments of economic warfare and continued so to function in World Wars I and II. However, new methods of depriving the enemy of supplies were developed, such as long-distance blockade and various forms of control at the ship's point of departure rather than in the course of its passage on the high seas. In spite of these innovations, which proved very effective, prize courts operated in England, France, Germany and many other countries. However, no prize courts operated in the United States during either World War I or II. In World War I, the president, authorized by the congressional joint resolution of May 12, 1917 (55 Stat. 261), took over about 100 German and Austrian ships lying in U.S. ports. In the Versailles treaty of June 28, 1919, Germany waived all claims arising from requisitioning, loss or damage of German ships. In World War II, the U.S. congress, proceeding in a similar fashion, enacted the *Idle Foreign Vessels act* (1941), which applied to all enemy and neutral vessels (55 Stat. 242). Some 80 ships, including the French liner "Normandie" were requisitioned pursuant to this act, which also provided for compensation. The U.S. experience has been summarized thus:

The history of the matter shows that the policy of the United States has tended to avoid resort to capture and prize, and to substitute . . . gentler legal devices such as requisition for use or title upon promise or payment of just compensation. It is a fact that from 1899 to 1945, including six years of the two great wars, no prize ship or cargo was brought into a United States prize court for adjudication. Those who guide our policy . . . have employed other methods of bringing about the end result of getting foreign ships and cargoes into the war service of the United States. Thus our country has maintained its position of endeavoring to lead the world towards a general law or rule of immunity from capture or destruction of peaceful merchantmen and cargoes not contraband. (Arnold W. Knauth, "Prize Law Reconsidered," *Columbia Law Review*, p. 69 [1946].)

On the other hand, the policy against enemy merchant ships and cargoes was expressed in the official United States Navy dispatch of Dec. 7, 1941: "Execute unrestricted air and submarine warfare against Japan." It was estimated that more than 2,000 Japanese merchant ships were sunk, of which more than one half were destroyed by submarines. Total war by air and on the sea against enemy shipping and stringent controls at the source of neutral shipping, reinforced by a comprehensive concept of contraband and of enemy destination, it was believed, might well reduce the scope and significance of both prize courts and prize law in a subsequent global conflict.

In a limited conflict, however, prize courts and prize law continued to render the traditional service as was evidenced by the establishment of a prize court in Egypt in 1948 following the outbreak of hostilities in Palestine. On Sept. 25, 1955, the United States chief of naval operations promulgated the *Law of Naval Warfare* as the official United States navy manual on the subject (NWIPIO-2, reproduced as an appendix in the volume by Robert W. Tucker cited in the bibliography).

PRIZREN, a town of the Kosovo-Metohija autonomous region of the Socialist Republic of Serbia, Yugos., lies on the Bistrica River in the foothills of the Sar Planina, 75 km. (47 mi.) SW of Pristina by road. Pop. (1961) 28,062, a large proportion being Albanians. Prizren is the seat of Orthodox and Roman Catholic archbishops and has a Serbian theological seminary. The town is most picturesque; its chief buildings are the citadel and many churches and mosques. The Church of the Virgin Mary was converted in 1756 into a mosque and many of its beautiful frescoes were damaged. In 1920 the building was restored to its original purpose.

Under the Romans the town was known as Theranda; under Byzantium as Prizdrijan. In the 14th century it became the capital of the Serbian kings and emperors, minted its own coinage, and had a flourishing trade with Dubrovnik. It passed from the Turks to the Serbs in 1913. (V. DE.)

PRO, MIGUEL (MIGUEL AGUSTÍN PRO-JUÁREZ) (1891-1927), Jesuit victim of the religious unrest in Mexico, was born on Jan. 13, 1891, at Concepción del Oro, Zacatecas. He had some Indian blood, and his father was a wealthy mining director. He entered the Society of Jesus in 1911; in October 1914 the anticlerical measures under Pres. Venustiano Carranza obliged him, with other students for the Jesuit priesthood, to leave Mexico for California. He continued his studies in Spain, Nicaragua, and at Enghien (Belgium), where he was ordained in 1925. He returned to Mexico, now under the religious persecution of Pres. P. Calles, in 1926 and for 15 months carried on his work as a priest among the people of Guadalupe with agents constantly searching for him. Every morning he offered mass secretly in the presence of many faithful. He preached in backyards, garages, factories, strengthening the faith of thousands, refusing no one who came to him for spiritual or material succour and supporting more than 100 poor families on the alms he could beg. In November 1927 the police discovered his hiding place; he was falsely accused of complicity in a bomb plot against Pres. Alvaro Obregón and on Nov. 23 was summarily shot. His connection with the international movement of the Jocsists, or Young Christian Workers, formed while he was in Belgium before ordination, helped spread his fame rapidly.

PROA: see BOAT.

PROBABILISM, in casuistry, is the view that, where one does not know whether an action would be sinful or permissible, one may rely on a probable opinion for its permissibility even though the more probable opinion is for its sinfulness. The word "probable" must here be understood to mean either "provable" (i.e., logically sound), when opinions are said to have "intrinsic probability"; or "approvable" (i.e., sponsored by some recognized authority), when they have "extrinsic probability." Formulated in 1577 by Bartolomé de Medina (c. 1527-80), a Dominican of Salamanca, probabilism was fast developed by the Jesuits. The Jansenists, who maintained that in doubtful cases of conscience one should take the safer view against permissibility (tutorism rigorism), attacked the benignity of the Jesuit confessors as leading to laxity of morals (see Pascal's *Lettres provinciales*). The excesses of probabilism were condemned by Pope Alexander VII (1666, 1667) and, more forcefully, by Pope Innocent XI (1679). Probabilism, which enjoins following the more probable opinion, was predominant in the 18th century before the formulation of equiprobabilism by Alfonso Maria de' Liguori (q.v.). See also CASUISTRY.

PROBABILITY. Of the precise meaning of probability there are conflicting views among experts (philosophers, mathematicians, statisticians). The reasons for this may be partly grasped from a survey of the various channels through which a scientific concept of probability has emerged.

Commercial insurance against risks was developed in the Italian cities of the early Renaissance. The theoretical foundations of life insurance were laid in the 17th century. John Graunt in 1662 drew attention to the stability of statistical series obtained from registers of deaths. Soon after, the astronomer Edmund Halley (1656-1742) showed how to calculate annuities from mortality tables (see ANNUITY).

Another early reason for interest in probability was in connection with the weight of evidence in legal procedure. The theory of judicial evidence occupies a prominent place in probability mathematics up to the mid-19th century.

Mathematical problems relating to games of chance had been considered, though with minor success, by Luca di Paciolo, Gerolamo Cardano (Jerome Cardan), Niccolò Tartaglia, and other mathematicians of the Renaissance. The subject was developed into a "geometry of the die" (*aleae geometria*) by Blaise Pascal, Pierre de Fermat, and Christiaan Huygens in the 17th century. Fermat treated the problems within a general theory of combinations, to become further developed by the Swiss mathematician Jakob Bernoulli. The latter can be regarded as the founder of probability theory as a branch of mathematics: his posthumously published *Ars conjectandi* (Basel, 1713) can be said to aim at a fusion of the a priori methods of combinatorial probability and the a posteriori methods of early statistical theory. The research on probability done by 18th-century mathematicians culminated in the immense work of Pierre Simon Laplace, the founder of a tradition that dominated the subject throughout the 19th century.

Laplace advocated a strictly deterministic view of the universe: an omniscient intelligence ("Laplace's demon") would be able to predict the course of nature in minutest detail with infallible accuracy. On this view, probability enters into a science of nature only as a theory of errors; i.e., as a systematic study of the deviations from a mean which appear in repeated measurements of a quantity. This study was developed by Laplace, by A. M. Legendre, and by C. F. Gauss (the normal law of error and the method of least squares). The mathematical calculus of probability soon provided tools for handling statistical material in connection with public finance, health administration, the conduct of elections and other social matters besides insurance. The marquis de Condorcet and later the astronomer Adolphe Quételet were champions of a social science on a statistico-probabilistic basis. From the middle of the 19th century, probability gradually gained ground as a part of physical theory. It first appeared in the theory of heat, J. C. Maxwell in 1860 deduced the familiar

gas laws from underlying probabilities for the distribution of positions and velocities over the molecules. Ludwig Boltzmann (1877) interpreted the irreversibility of thermal processes as a tendency toward a most probable distribution of the energies of the molecules. The rise of quantum mechanics saw the theory of radiation put on a probability basis by Max Planck (1900). With the further development of quantum physics, probability invaded atomic theory. By the middle of the 20th century the deterministic view of nature was thought in some quarters to be in process of being replaced by a probabilistic view. The concept of probability had become one of the fundamental notions of a modern science and philosophy of nature. This gave a new urgency to the need for clarifying the structure and meaning of the idea.

The Abstract Calculus of Probability.—In the course of the development already outlined, several definitions of probability were suggested. Accordingly, alternative methods were devised for basing the edifice of probability mathematics on those definitions. These alternative calculi take different views of the meaning of their fundamental notion, but they agree, by and large, in having a common logical structure.

These observations offer a starting point for attempts to create an abstract calculus of probability. It abstracts from the various interpreted calculi their common structure, the formal properties of which it studies independently of any definition of probability.

In the abstract calculus developed by the Russian mathematician A. N. Kolmogorov (1933), probability figures as a function of sets. This theory, which has found much favour among mathematicians, incorporates probability mathematics within the general theory of measurable sets of points.

Abstract calculi of a type that might be called logistic were constructed by J. M. Keynes (1921), Hans Reichenbach (1932), Harold Jeffreys (1939), and other authors. In these systems probability figures as an undefined logical relation between propositions or attributes (propositional functions, classes, sets).

Let us introduce, following Keynes, the symbol a/h , which can be read as "the probability of a given h ." It is often convenient to speak of a as an "event" and of h as some "conditions" or "data" or "evidence." We need not assume that any pair of propositions (or attributes) determines a numerical value of the functor. But if there is a numerical probability, it should, for noncontradictory data, satisfy the following four postulates: (1) $a/h \geq 0$; (2) $h/h = 1$; (3) $a/h + (\text{not-}a)/h = 1$, the principle of complementarity; and (4) $(a \text{ and } b)/h = a/h \times b/(h \text{ and } a)$, the general multiplication principle. These four postulates suffice, with the aid of a few principles of a subordinate character, for the erection of the whole fabric of probability mathematics.

From the first, second and third postulates it follows that all probability-values are in the interval from 0 to 1 inclusive.

From the third with the aid of the fourth, we can prove the general addition principle: $(a \text{ or } b)/h = a/h + b/h - (a \text{ and } b)/h$.

If a and b are mutually exclusive alternatives, the probability of their joint occurrence is 0. Thus for exclusive a and b we have the equality: $(a \text{ or } b)/h = a/h + b/h$. This is called the special addition principle.

If $a/h = a/(h \text{ and } b)$, we say that a is independent (for probability) of b (in h). The notion of independence is of great importance to the further development of the calculus. It follows from the fourth postulate and the definition of independence that for independent a and b we have the equality: $(a \text{ and } b)/h = a/h \times b/h$. This is called the special multiplication principle.

The Frequency Theory of Probability.—This is the view that, popularly speaking, the probability of a given h means the relative frequency with which the event a takes place when the conditions h are fulfilled. The probability of a given h , in other words, is the proportion of h situations that lead to a events.

The frequency view of probability has a long history. Aristotle defines "a probability" as being "what men know to happen or not to happen, to be or not to be, for the most part thus and thus." A similar opinion was entertained by writers of the 17th and 18th centuries, who were interested in statistics or in a "theory of evidence."

The history of probability mathematics from Jakob Bernoulli

to Laplace and his followers is allied to a different view of the meaning of probability. The rebirth of the frequency theory followed a criticism of the foundations of the Laplacean calculus, particularly of the use of the so-called principle of indifference for the determination of probability values (see below). The attack was launched by R. Leslie Ellis, J. Stuart Mill, and A. A. Cournot in publications of the same year 1843. The frequency conception of probability was first worked out into a mathematical theory by John Venn (1866).

Early proponents of the frequency theory spoke of probability as a relative frequency "in the long run." This loose way of speaking is not very satisfactory. Venn was the first to define an event's probability as the limiting value which its relative frequency approaches as the number of occasions is indefinitely increased. An improved version of this frequency-limit theory was presented by Richard von Mises in 1919; another later well-known adherent of the theory is H. Reichenbach.

Von Mises also thought that a probability cannot be simply (the limiting value of) a relative frequency and added the qualification that the event ought to be irregularly or randomly distributed in the series of occasions, relative to which its probability is measured. This demand of randomness he called the principle of excluded gambling systems.

It is a great merit of Von Mises to have stressed the importance of the idea of random distribution to a frequency theory of probability. But with this idea he introduced a considerable difficulty into the theory. How is random distribution to be defined? The definition originally proposed by Von Mises has been accused of inconsistency, but it is doubtful whether any of the alternative definitions proposed by other writers (H. Reichenbach, K. Popper, A. Copeland, A. Wald) can be regarded as satisfactory.

The demand of randomness is relevant to the question of the adequacy of the frequency view as a proposed analysis of the meaning of probability. But it is not relevant to the question of the mathematical correctness of the interpretation of abstract probability in terms of frequencies (either in finite or infinite series). It may easily be verified that a frequency definition satisfies the postulates of the abstract calculus.

Even if we disregard difficulties caused by the notion of randomness, many more objections can be raised against the frequency view. Nevertheless, some form of a frequency theory is thought by many writers to offer the best account (at least for a large category of cases) of the relation between abstract probability and empirical reality.

The Range Theory of Probability.—This theory can, in its simplest form, be explained as follows: We analyze h into a number n of alternative conditions. That h is fulfilled means that either h_1 or . . . or h_n is fulfilled. Some of these alternatives, say m , entail the occurrence of a , the remaining ones entail the occurrence of not- a . Using a traditional terminology, we call the first group of alternatives favourable to a and the second unfavourable to a . The probability of a given h is the ratio $m:n$ of the number of favourable alternatives and the number of all alternatives.

This, if we omit an important qualification to be discussed presently, is substantially the definition of probability that emerged from the mathematical treatment of games of chance and was canonized in the theory of Laplace. We may refer to it as the classical form of the range definition.

It is natural to call the (mutually exclusive) alternatives covered by a proposition (or an attribute) its range. The classical definition given above can be generalized as follows: The probability of a given h is the ratio of the measure of the range of h -and- a and the measure of the range of h alone.

The notion of a range (in German, *Spielraum*) was introduced into probability theory by Johannes von Kries (1886). It was used to define probability as a logical relation between propositions by Ludwig Wittgenstein (1922). Substantially the same definition had been given by Bernard Bolzano as early as 1837. A generalized form of the Bolzano-Wittgenstein definition was suggested by F. Waismann (1929) and was further developed and extensively studied by Rudolf Carnap (1950). The Waismann-Carnap definition is independent of any specific way of measuring the ranges.

The range definition, both in its classical and in its generalized form, satisfies the postulates of abstract probability. The definition, no doubt, is mathematically correct. But does it give an adequate account of the meaning of probability?

The Principle of Indifference.—The main difficulty confronting a range theory of probability concerns the measurement of the ranges. This difficulty is allied to the question of how to analyze propositions (or attributes) into alternatives. Usually there are several possibilities open for the choice of a measure and the analysis of the data into alternatives.

The classics of probability theory were aware of these difficulties and the first one to discuss the matter fully was Jakob Bernoulli. He stressed that the alternatives into which h (of the probability-functor) is analyzed ought to be equally possible; *i.e.*, "each case ought to have the same facility as any other case of coming about." This condition of equipossibility in the cases was usually added to the classical range definition of probability. The condition, it will be noted, is tantamount to a principle of measuring ranges.

But what does equipossibility mean and on what conditions may we rightly pronounce cases equally possible? In answer to the latter question Jakob Bernoulli laid down a rule which has become known under the names of the principle of insufficient reason, the principle of equal distribution of ignorance or the principle of indifference (Keynes). In its classical version this principle states that two cases are equally possible if no reason is known why the one case rather than the other should come about.

Reliance on a principle of indifference for measuring ranges (probabilities) has a certain *prima facie* plausibility in games of chance, where there usually is complete agreement among experts as regards the right analysis of the situations into alternatives of equal possibility. In cases which present no obvious analogy to games of chance, reliance on the principle becomes dubious. It was the use of it made by Laplace and his followers, particularly for the notorious doctrine of inverse probability (*see* below and also *INDUCTION*), that, in the middle of the 19th century, provoked criticism of the foundations of the entire classical fabric of probability theory. Among the earlier critics of the principle of indifference mention should be made of R. Leslie Ellis, G. Boole, C. S. Peirce, and J. von Kries.

In modern times J. M. Keynes discussed the principle acutely and in detail. Severely criticizing its unguarded uses, he also attempted to refashion the principle and to make clear its relevance to any philosophy of probability. Warranted use of the principle is tied to the question of symmetry in the unit alternatives under consideration; and the problem of symmetry in its turn is tied to the problem of an ultimate analysis of propositions (attributes) into alternatives. Any judgment of symmetry or ultimacy, as it presupposes that all relevant information about the cases has been taken into account, is, negatively, a judgment of irrelevance or independence for probability among propositions (attributes). Any pronouncement on irrelevance involves, so Keynes thought, an "element of direct judgment or intuition."

The principle of indifference has usually been discussed in connection with the classical range definition, to which it was traditionally regarded as a necessary supplementation. It should, however, be observed that the problems connected with this principle recur, *mutatis mutandis*, within any theory which defines probability in terms of the relative magnitudes of ranges.

The Belief Theory of Probability.—Many authors in the past spoke of probability as a degree of belief or of certainty. F. P. Ramsey (1926) and, somewhat later, B. de Finetti (1937) made a systematic attempt to base the mathematical theory of probability on the notion of partial belief. Both authors take as their point of departure the old idea of measuring a person's belief by proposing a bet and observing the lowest odds that he will accept. It may be shown that a person who distributes his partial beliefs (*i.e.*, subjective assignments of probabilities) contrary to the laws of the calculus could have a so-called Dutch book made against him and would then stand to lose in any event. Because of this, the laws of probability may be called rules for consistent (coherent) sets of degrees of belief.

Ramsey, moreover, made an ingenious effort to generalize the

above procedure of measuring beliefs. A bet can be regarded as an option between goods, and accepting lowest odds as a reflection of an attitude of indifference in an option. A distribution of our partial beliefs contrary to the laws of probability, Ramsey says, "would be inconsistent in the sense that it violated the laws of preference between options, such as that preferability is a transitive asymmetrical relation."

The ideas of Ramsey and De Finetti were later taken up by L. J. Savage (1954), who became the founder of a subjectivist or personalist school in modern theory of probability and statistics. The combination of probabilistic ideas with the value-theoretic notions of preference and utility has had fruitful applications to the mathematical study of economic and related forms of human behaviour. Acknowledgment of this fact does not exclude that one may take a somewhat critical view of the epistemological and logical basis of the belief theory of probability.

Is Probability Subjective or Objective?—The subjectivist conception of probability as a degree of belief is often contrasted with the objectivist conception of the notion as either a relative frequency or a ratio of measures of ranges. It is questionable, however, whether one can maintain a sharp contrast between objectivism and subjectivism in the philosophy (epistemology) of probability.

As we have seen, supporters of the frequency view have found it necessary, to reach an adequate analysis of probability, to combine their definition of the concept with the idea of a random distribution of events on a series of occasions. Supporters of a range theory again have, for the same purpose, had recourse to some form of a principle of indifference for the determination of equipossibility in certain unit alternatives. The question may be raised whether randomness and equipossibility can be satisfactorily accounted for independently of reference to a state of knowledge or ignorance. If the answer is negative, we shall have to admit that an adequate account of the meaning of probability cannot be given in purely objectivist terms.

On the other hand, the belief theory does not necessarily entail an identification of probability with belief as a psychological phenomenon. The attitudes in options between goods may be said to reveal subjective estimations of probability. But the derivation of the laws of probability within the belief theory does not confer on them the status of psychological laws of believing. It rather makes them standards of rationality (consistency) in the distribution of beliefs or in preferences. It would therefore be an oversimplification to regard the belief theory as an account of probability in purely subjectivist (that is, psychological) terms.

Bernoulli's Theorem.—Let us assume that the probability for the occurrence of an event a on a certain occasion of h is not affected by its occurrence or nonoccurrence on previous occasions of h . The occurrences of a , in other words, are independent for probability of one another. And let us assume that this probability is p . A simple use of the special multiplication and addition principles can now be made for calculating the probability that the event a will, on n occasions of h , be realized with a relative frequency in the interval $p \pm \epsilon$. From considerations about this second-order probability we can prove that:

1. The most probable value of the event's relative frequency on n occasions is that value which comes nearest to its probability p .
2. The probability that the event's relative frequency on n occasions will deviate from its probability p by less than a given amount ϵ , however small, approaches 1 as a limit when n is indefinitely increased. Thus, popularly speaking, in the long run the event will almost certainly be realized with a relative frequency corresponding to its probability.

An example will illustrate this asymptotic character of the increasing probability. The probability of head and tail in tossing with a normal coin is $\frac{1}{2}$. The results are independent for probability: no combination of head and tail in previous tosses will influence the probability of getting head or of getting tail in the next toss. A simple calculation shows that the probability of getting 49, 50, or 51 heads in 100 tosses is approximately 0.16; the probability of getting between 490 and 510 heads in 1,000 tosses is 0.47; and the probability of getting between 4,900 and 5,100 heads

in 10,000 tosses is 0.95. In other words: in 10,000 tosses it is already almost certain that the proportion of heads will deviate by less than 0.01 from its probability $\frac{1}{2}$.

This remarkable theorem is known as Bernoulli's theorem. It is chronologically the first member of a class of propositions called the laws of great numbers. The name was introduced by Siméon Denis Poisson (1837).

Inverse Probability.—In 1763 Thomas Bayes proved that, if m/n is the relative frequency of an event on n independent occasions, then m/n is also the most probable value of the event's probability, provided that any value of this probability is initially (a priori) as probable as any other value. The same theorem was proved independently by Laplace in 1774. Laplace also proved that, on the assumptions mentioned, it will in the long run become almost certain that the probability of the event coincides with its relative frequency.

The Bayes-Laplace theorem is the inversion of Bernoulli's theorem and the cornerstone of the classical doctrine of inverse probability for the estimation of probabilities on the basis of frequencies. The doctrine was developed and put to extensive use by Laplace and his followers. It was thought to be of great relevance to the problem of induction.

The Achilles' heel of inverse probability is its dependence on initial or a priori probabilities. These were in the classical doctrine often established by deplorably uncritical use of the principle of indifference. The doctrine was challenged in the 19th century, particularly by early proponents of the frequency view. The use of inverse probability is still a matter of debate. Some researchers, among them R. A. Fisher, have altogether rejected it.

Asymptotic Probabilities and the Principle of Moral Certitude.—It was often thought in the past that, by virtue of Bernoulli's theorem, events will, in the long run, happen in numbers proportional to the probabilities (A. De Morgan, 1838). But this is a serious mistake. The theorem only says that it becomes increasingly probable that the frequency coincides with the probability. And this, by itself, does not warrant any conclusion about actual frequencies, not even in the long run.

The error latent in the idea that Bernoulli's theorem provides a bridge from a subjectivist conception of probability as a degree of certainty to an objectivist conception in terms of frequencies was first clearly seen and conclusively criticized by R. Leslie Ellis (1843). There were many relapses into the error afterward, but today the correctness of the criticism is universally admitted.

There is, however, another way of using Bernoulli's theorem and other asymptotic principles of probability (laws of great numbers) as a bridge from (uninterpreted) probabilities to statistical frequencies without committing a logical error. It may be briefly indicated as follows:

Let us assume that, either from observations about frequencies or from considerations about ranges or from some other source, we frame a hypothesis about the probability of a given b . From this hypothesis we calculate that it is "almost" or, as Bernoulli would have said it, "morally" certain (say probable to degree 0.95) that in a series of n trials the relative frequency of the event will deviate from its probability by less than a small fraction (say 0.01). In other words, it is "most unlikely" (morally impossible) that the frequency will fall short of the hypothetical probability by more than this fraction. Now we may adopt a maxim that very improbable events are "practically excluded" or that "moral certainty" should be treated as equal to full certainty. Consequently, if the event's frequency nevertheless deviates from the hypothetical value by more than the fraction in question, we say, not that something very improbable has happened, but that our probability hypothesis has to be rejected.

The proposed maxim was in fact suggested already by Bernoulli. It might be called Bernoulli's principle of moral certitude. Its adoption seems to be in good accord with actual use of probability calculations for scientific and applied purposes. And it partially explains why it is possible, without detriment to the applications of probability, to suspend judgment as regards the meaning of this controversial notion. The calculus is a vehicle which takes us from hypothetical probabilities to predicted frequencies. If the

observed frequencies conflict with the principle of moral certitude, the hypotheses are modified or rejected. The boundaries of moral certitude are, of course, elastic; and whether we wish provisionally to fix them at one value rather than at another will depend upon a multitude of circumstances peculiar to each case. Such circumstances are the amount of statistical evidence at hand, the possibilities of repeated trials and the facility with which dependencies between occurrences can be controlled. Among them are also considerations of an ethical nature relating to the gains and losses which we may incur by choosing one probability hypothesis rather than another as a basis of our actions.

Has "Probability" One or Many Meanings?—Compare the following uses of probability: (1) "the probability of a normal six-sided die turning up 'six' is $\frac{1}{6}$ "; (2) "the probability that Shakespeare wrote the plays commonly attributed to him is overwhelming"; (3) "Fresnel's experiment increased the probability of the undulatory theory of light." Does "probability" mean the same in all the three statements?

According to Hans Reichenbach, one of the chief proponents of the frequency theory in modern times, there is only one (scientific) meaning of probability. A statement of the second type exemplified above, which concerns the probability of an individual event, is literally meaningless, but may be reinterpreted as a statement about that which usually is the case under similar circumstances. Statements of the third type, again, which attribute probability to general propositions (laws of nature, theories, hypotheses) may, according to Reichenbach, be given a frequency interpretation as referring either to a proportion of successful predictions, or to a proportion of true theories within a class.

A unitary view of probability was also taken by J. M. Keynes, though on quite different grounds. According to Keynes, the difficulties presented by cases such as the second and third types exemplified above would indicate that probability is a wider notion than the concept which figures in a frequency theory or even in any theory which requires probability to be a measurable quantity. In its wide sense, probability is a (not necessarily measurable) degree of rational belief.

Those who have advocated a dualistic view of probability have usually wished to contrast cases of the third type, or the probability of laws of nature, with other types of probability. Jakob Friedrich Fries (*System der Logik*, 1811; *Versuch einer Kritik der Principien der Wahrscheinlichkeitsrechnung*, 1842) called the probability of laws "philosophical probability" and contrasted it with "mathematical probability." This distinction was adopted by many logicians and philosophers of the 19th century (E. F. Apelt, A. A. Cournot, M. W. Drobisch). Philosophical probability was thought to be nonnumerical in principle. A similar position found favour with many 20th-century authors: Bertrand Russell (1948) contrasts "credibility" and "mathematical probability"; W. C. Kneale (1949), "acceptability" and "chance"; R. B. Braithwaite (1953), "reasonableness" and "probability."

A dualistic view of a somewhat different nature was developed by Rudolf Carnap (*Logical Foundations of Probability*). Of the two concepts of probability that he distinguishes, the first (which he also calls "degree of confirmation") is probability in the sense of a range theory; the second is probability in the sense of a frequency theory. Carnap tries to reconcile the rival claims of the two theories by assigning to each concept of probability its proper field of application. In view of the difficulties, however, which both theories encounter as proposed analyses of probability, it cannot be taken for granted that this reconciliation is altogether satisfactory. See also PROBABILITY, MATHEMATICAL.

PROBABILITY, MATHEMATICAL. Mathematical probability is an attractive, thriving, and respectable part of mathematics (some say the gateway to its deepest mysteries). It has a well-defined basis in a system of axioms governing the relations of what are called probabilities in a probability algebra or calculus; the probabilities themselves are real numbers between zero and one (inclusive). The most famous axiom system has been formalized by A. N. Kolmogorov, and will be given later. It should be noted that the idea of probability is primitive, beyond definition, distinct from philosophical probability (see **PROBABILITY**), and immune to the controversy that has plagued philosophers. However, there are similarities; probability in its ordinary use is related to uncertainty. In mathematics, the character of the uncertainty is spelled out completely by specifying the alternatives in question, just as any sensible bet specifies exact terms of payoff. In coin tossing, for example, the usual specification is that the coin must fall head or tail; falling on edge, rolling away, and all other bizarre possibilities are ruled out. In mathematical terms, let the event coin-falls-head be labeled E_1 (E for event), the event coin-falls-tails E_2 ; then the uncertainty only concerns which of the events E_1, E_2 occurs. If it were desired to include bizarre possibilities, corresponding events E_3 (coin falls on edge), E_4 (coin rolls away), and so on, would be required for complete mathematical description. The set of events $\{E_1, E_2, \dots\}$ is commonly called a sample space, and the events are called points of the space. This terminology seems odd for discrete alternatives (finite sets of events), but it is used for uniformity, to make the theory as general as possible. Although the points of the sample space are called events, they are not necessarily objectively observable events; they also may be imagined (as in so-called conceptual experiments) if this serves a purpose. In either case, the weight or measure assigned to a point of sample space is said to be its probability. Then the axiom system determines the probabilities of all sets of points in the space. Note that the assignment of probabilities to points of the space is under no restraint other than that arising from the axioms. Naturally, simple assignments come first. When the sample space has n discrete points, the simplest assignment is $1/n$ for each of the n points, that is, the outcomes are equally probable; this is a version of what is called the Laplace rule (after Pierre Simon Laplace, whose treatise, *Théorie analytique des probabilités* [1812], is one of the great probability classics). While the direct use of this and similar simple probability models may be hard to justify (e.g., to a philosopher whose job is to look for trouble), there are many indirect uses, including the part the models play in building a coherent body of theory, which commend them to mathematical attention.

To avoid the intricacy and subtleties of measure theory, the exposition below (following the lead of William Feller, whose *Introduction to Probability* . . . is a modern classic) is limited to discrete sample spaces. A sample space is called discrete if it contains a finite or infinite number of points that can be arranged in a simple sequence E_1, E_2, \dots (that is, are denumerable), with E_i a point of the space. With each point E_i of the sample space, there is associated a real number between zero and 1, inclusive, called the probability of E_i , and denoted by $\Pr(E_i)$, where

$$\Pr(E_1) + \Pr(E_2) + \dots = 1$$

However there are a few places where results grounded in non-discrete sample spaces appear; their justification is left to the reader's intuition or background. (See also **POINT SET**.)

Elementary Definitions and Theorems.—For uniform terminology, all points and sets of points of the sample space are called events, in keeping with the notion, given above, of the sample space as a specification of experimental outcomes. If A is an event, its probability is written as $\Pr(A)$; $\Pr(A)$ is the sum of the probabilities of all points in A . The complement of A is the event consisting of all points not contained in A and is denoted by \bar{A} , and the complementary probability to $\Pr(A)$ is $\Pr(\bar{A})$,

where $\Pr(A) + \Pr(\bar{A}) = 1$, or $\Pr(\bar{A}) = 1 - \Pr(A)$. This formula expresses the fact that either A or its complement must occur.

With any two events A and B there may be associated two new events: the compound event AB in which both A and B occur, and the union of A and B , denoted by $A \cup B$, in which either A or B or both occur. (The symbol \cup is sometimes called cup, and is used to mean the set consisting of points belonging either to A or B or both; it is generically similar to the plus sign and indeed when A and B have no points in common Kolmogorov replaces $A \cup B$ by $A + B$.) The probabilities of these new sets are denoted by $\Pr(AB)$ and $\Pr(A \cup B)$. Of course these operations may be extended to as many sets as desired; the meaning of the event $ABC \dots$ is that all A, B, C, \dots occur, and of $A \cup B \cup C \dots$ that either A or B or C or . . . or all of A, B, C, \dots occur. A compound event AB may be regarded as occurring in time sequence: first A , then B ; then $\Pr(AB) = \Pr(A)\Pr(B|A)$ serves as a definition of the conditional probability $\Pr(B|A)$, which is read as the probability of B given A . If $\Pr(AB) = \Pr(A)\Pr(B)$, then events A and B are statistically independent (or independent, for short). For n events, Kolmogorov gives $2^n - n - 1$ equations of independence, which may be summarized by saying that every k -combination, $k = 2, 3, \dots, n$, of the n events must be independent. (A k -combination is an unordered selection of k things.)

With these definitions are associated certain basic theorems. First, the Theorem of Compound Probability (or Multiplication Theorem) is given by

$$\Pr(A_1 A_2 \dots A_n) = \Pr(A_1) \Pr(A_2 | A_1) \Pr(A_3 | A_1 A_2) \dots \Pr(A_n | A_1 A_2 \dots A_{n-1})$$

This equation is a generalization of the equation used above to define conditional probability. It provides an easy way to compute compound probabilities when the events may be regarded as occurring in sequence, and the conditional probabilities are easier to compute. Note that the conditional probability of event B when A is known to have happened may be quite different from the unconditional probability $\Pr(B)$. Next if events A_1, A_2, \dots, A_n are mutually exclusive events that exhaust all possibilities, the Theorem of Total Probability states that for any event X

$$\Pr(X) = \Pr(A_1)\Pr(X | A_1) + \Pr(A_2)\Pr(X | A_2) + \dots + \Pr(A_n)\Pr(X | A_n)$$

Finally there is Poincaré's formula, a probability version of the Principle of Inclusion and Exclusion (see **COMBINATORIAL ANALYSIS: Discordant Permutations**), which applies to compounds of complementary events. For two events A_1 and A_2

$$\Pr(\bar{A}_1 \bar{A}_2) = 1 - \Pr(A_1) - \Pr(A_2) + \Pr(A_1 A_2)$$

The right-hand side may be abbreviated $\Pr[(1 - A_1)(1 - A_2)]$, if it is understood that the internal multiplication is to be performed first, and the terms separated by the rule

$$\Pr(A + B + \dots) = \Pr(A) + \Pr(B) + \dots, \text{ while } \Pr(1) = 1.$$

With these conventions, Poincaré's formula for n events may be written in abbreviated notation as

$$\Pr(\bar{A}_1 \bar{A}_2 \dots \bar{A}_n) = \Pr[(1 - A_1)(1 - A_2) \dots (1 - A_n)]$$

Note that $\bar{A}_1 \bar{A}_2 \dots \bar{A}_n$ is the complementary event to $A_1 \cup A_2 \cup \dots \cup A_n$ so that

$$\Pr(\bar{A}_1 \cup A_2 \cup \dots \cup A_n) = 1 - \Pr[(1 - A_1)(1 - A_2) \dots (1 - A_n)]$$

Simple Illustrative Examples.—*Coin Tossing.*—Consider tosses of two coins. The outcomes may be labeled HH, HT, TH, TT (H for head, T for tail); these are the points E_1, E_2, E_3, E_4 of the sample space. The event two-heads is E_1 ; its complement, the less-than-two-heads is the union of E_2, E_3 and E_4 ; that is, the set $\{E_2, E_3, E_4\}$. The event just-one-head is the set $\{E_2, E_3\}$. If all its complement no-heads-or-two-heads is the set $\{E_1, E_4\}$. If the four sample points have probability $\frac{1}{4}$, the probabilities of the events just defined are each $\frac{1}{2}$, while the probability of two heads (or two tails) is $\frac{1}{4}$, and the probability of its complement is $\frac{3}{4}$. If all outcomes are regarded as compound events, and are equally

probable, then the probability of head equals the probability of tail equals $\frac{1}{2}$; otherwise, if head falls with probability p and tail falls with probability q ($p + q = 1$, necessarily), then the outcomes have respective probabilities (in the order written) p^2, pq, q^2 . Note that $p^2 + pq + q^2 = (p + q)^2 = 1$. If the two coins are regarded as tossed successively, so that the outcomes represent sequences in time, another set of events may be considered; these are defined by first-appearance-of-head or number-of-tosses-up-to-first-head (often called a first-crossing or waiting-time problem). Since head may appear first on the first toss, on the second toss, or not at all, the sets of sample points for the three events are, respectively, (E_1, E_2) , E_3 , and E_4 . If the probability of head at each toss is p , the respective probabilities are p , pq , and q^2 . Similar results appear in successive tosses of n coins that are alike (or n independent tosses of a single coin), as will appear in the discussion of the negative binomial distribution later.

Arrangements of Distinct Objects.—Consider the six ordered arrangements (permutations) of three objects a , b , and c ; namely abc , acb , bac , bca , cab , cba . These may be taken as the points $E_1, E_2, E_3, E_4, E_5, E_6$ of the sample space. The event a -in-first-place is the set $\{E_1, E_2\}$. Regarding any arrangement as a displacement of the natural order abc , the event no-object-displaced is the point E_1 ; the event one-object-displaced contains no points, since a displacement must interchange at least two objects; the event two-objects-displaced is the set $\{E_2, E_3, E_4\}$, and finally the event three-objects-displaced is the set $\{E_4, E_5\}$. The number of points in these successive sets is 1, 0, 3, 2, and these numbers are proportional to probabilities when the points of the sample space are equally probable.

Sampling Surveys.—A sampling survey is a procedure for obtaining statistical information. Suppose the survey is of handedness in people, and each sample has 100 members. Then each sample provides an integral number x (the number of left-handers in the sample, say), where x may be 0, 1, . . . , 100. The sample space consists of 101 points 0, 1, . . . , 100. Presumably if the survey takes sufficiently many samples, many of these points will appear with low frequency, many not at all. The relative frequencies found serve as a guide to the assignment of probabilities of the sample space, for use in other calculations.

Simple Probability Calculations.—Some probability calculations were made in the preceding section; a few more may be helpful.

Card Hands.—An ordinary poker or bridge deck consists of 52 cards, 13 of each suit (two black: clubs, spades; two red: diamonds, hearts) with face values 2, 3, . . . , 10, jack, queen, king, ace. Of the many probability calculations that may be made, consider the following. A bridge hand consists of 13 cards, and the number of different bridge hands is the number of combinations of 52 things taken 13 at a time, that is (see COMBINATORIAL ANALYSIS: *Permutations and Combinations*) the binomial coefficient

$${}_{52}C_{13} = \frac{(52)!}{(13)!39!} = \frac{52 \cdot 51 \cdot \dots \cdot 40}{13 \cdot 12 \cdot \dots \cdot 1}$$

If all hands are equally probable, consider the probability that a hand will contain all face values (not necessarily of the same suit). Since each face value may appear in any of the four suits, there are 4^{13} ways of choosing hands containing all face values and the probability in question is $4^{13}/{}_{52}C_{13} = 0.0001057 \dots$ or about 1 in 10,000.

Birthdays.—Birthdays are distributed throughout the year in a nonuniform way, and years themselves are of variable length. Assume equal probability for a birthday each day of a 365-day year, and consider the probability that in a group of r people, all birthdays are different. For r people the total number of possible birthdays (on the equiprobable assumption) is 365^r . Of these, the number in which all are unlike is $365 \cdot 364 \cdot \dots \cdot (365 - r + 1)$, since any one can be picked in 365 ways, the next in 364 (it must differ from the first), the third in 363, and finally the r th in $365 - r + 1$. If the expression $n(n-1) \dots (n-r+1)$ is abbreviated to $(n)_r$,

the probability in question is $(365)_r/365^r$ or

$$\left(1 - \frac{1}{365}\right)\left(1 - \frac{2}{365}\right) \dots \left(1 - \frac{r-1}{365}\right)$$

Multiplying this out and neglecting cross products leads to the approximation $1 - r(r-1)/730$. A closer approximation follows from taking natural logarithms ($q.v.$) and using the approximation $\log(1-x) \approx -x$. Then if the probability is denoted by p , $\log p \approx -r(r-1)/730$. This approximation is particularly apt in answering the question of how large r should be so that p is close to $\frac{1}{2}$. Using the approximation and $\log(\frac{1}{2}) = -\log 2 = -0.69315$ leads to $r(r-1) = 730 \log 2$; and r is about 22.6. With 22 people the probability that no two have the same birthday is a little larger than $\frac{1}{2}$, (specifically, 0.524), but for 23 people it is smaller (0.493).

Craps.—This is the ordinary dice game, played with two six-faced cubes; one of the dice is called a die. Each throw realizes a number (or "point") between 2 and 12, inclusive. The various ways of obtaining these sums are given in the table below. The table shows, for example, that there is only one way to get the sum 2; both dice must show 1; that is, 1,1. The table also shows that there are two ways to get the point 3, and so on.

2	3	4	5	6	7	8	9	10	11	12
1,1	1,2	1,3	1,4	1,5	1,6	2,6	3,6	4,6	5,6	6,6
	2,1	2,2	2,3	2,4	2,5	3,5	4,5	5,5	6,5	
		3,1	3,2	3,3	3,4	4,4	5,4	6,4		
			4,1	4,2	4,3	5,3	6,3			
				5,1	5,2	6,2				
					6,1					

and the relative numbers of ways for each point are

Point	2	3	4	5	6	7	8	9	10	11	12
Number	1	2	3	4	5	6	5	4	3	2	1

giving a total of 36 possible ways. A player wins if he throws 7 or 11 on the first throw, or, if having thrown one of 4,5,6,8,9,10 on the first throw, he "makes his point," that is, throws the same point before throwing 7. Alternatively, he loses if he makes 2, 3, or 12 on the first throw, or fails to make his point which may be any of 4,5,6,8,9,10. The sample space consists of the 36 pairs of numbers (n,m) , $n = 1,2,3,4,5,6$, and m likewise. If each of these has the same probability, the probability of winning may be calculated as follows. First, the probability of throwing 7 or 11 on the first throw is $6/36 + 2/36 = 2/9$. Next the probability of making a point with a probability of $x/36$ (where $x = 3$ for points 4,10; $x = 4$ for points 5,9; $x = 5$ for points 6,8) is

$$\frac{x}{36} \sum_{n=0}^{\infty} \left(1 - \frac{6}{36} - \frac{x}{36}\right)^n \frac{x}{36}$$

The first $x/36$ is the probability of throwing a point with probability $x/36$ on the first throw, the sum following is the probability that the throws intervening between this throw and the last throw give neither 7 nor the point, the last $x/36$ is the probability that the last throw (which may follow arbitrarily many intervening throws) is the same as the first. The sum is that of a geometric series and after simplification becomes $x^2/36(x+6)$. Hence the probability of making a point is

$$2\left[\frac{9}{36 \cdot 9} + \frac{16}{36 \cdot 10} + \frac{25}{36 \cdot 11}\right] = \frac{134}{495}$$

Adding $2/9$ to this makes the probability of winning $244/495$ which is about 0.493. The game is not fair in that the probabilities of winning and losing are not equal.

Random Variables, Probability Distributions, and Distribution Functions.—In the framework of the probability theory under description, "random variable" is a misnomer, as is evident in the definition: a function defined on a sample space is

called a random variable. Function is used in its mathematical sense, of course, and in the definition simply means that each point of the sample space is assigned a value in accordance with some function. Examples have already appeared; when coin tosses are considered by number of heads, the function assigns the value k to each point of the space that corresponds to k heads; when arrangements are considered by number of elements displaced, the function assigns k to each point of the space having k elements displaced.

Despite this confusing aspect, the term random variable is too firmly entrenched to be changed, and in ordinary usage its definition is as follows: X is a random variable (in a discrete sample space) if it assumes values x_1, x_2, \dots and to each of these values is assigned a probability: $\Pr(X = x_j) = f(x_j)$. Naturally (by the definition of a discrete sample space), $f(x_j) \geq 0$ and

$$f(x_1) + f(x_2) + \dots = 1$$

The set of probabilities $\{f(x_1), f(x_2), \dots\}$ is called a probability distribution. This term must be distinguished from the term distribution function, which is essential in the consideration of non-discrete sample spaces. A distribution function is any nondecreasing function $F(x)$ that tends to zero as x approaches minus infinity

FIG. 1.—DISTRIBUTION FUNCTION FOR DISCRETE SAMPLE SPACES

and to 1 as x approaches plus infinity; the distribution function $F(x)$ of random variable X is $\Pr(X \leq x)$. For a discrete random variable

$$F(x) = \Pr(X \leq x) = \sum_{x_j \leq x} f(x_j)$$

$F(x)$ has the form of a staircase with risers of size $f(x_j)$ at each point x_j ; the staircase is entirely included between the lines $F(x) = 0$ and $F(x) = 1$ (see fig. 1). The continuous curves with which engineers and statisticians are more familiar are obtained by increasing the number and density of the points x_j in the way familiar from the limiting procedures of the differential calculus (see fig. 2).

A concept closely associated with probability distribution is its generating function; indeed generating functions were invented by

FIG. 2.—CONTINUOUS DISTRIBUTION FUNCTION

Laplace for their service in the probability calculus. The generating function of the discrete distribution given above is written as

$$P(t) = f(x_1)t^1 + f(x_2)t^2 + \dots + f(x_i)t^i + \dots$$

When the x_j are integers $P(t)$ is either a polynomial (q.v.) or a power series in t ; it is common to regard t as a real variable with a range such that the sum on the right exists (when the x_j are infinite in number), but for many uses of the generating function in probability and in combinatorial analysis, convergence questions are irrelevant.

Often it is important to know whether or not random variables

FIG. 3.—NORMAL DENSITY FUNCTION

are independent. The definition of independence is as follows: If n random variables X_1, \dots, X_n are defined on the same sample space, their joint distribution is given by a system of equations that assigns probabilities to all combinations $X_1 = x_{j_1}, \dots, X_n = x_{j_n}$ where x_{j_k} ranges over all possible values for X_k . The random variables are mutually independent if for any combination of values x_{j_1}, \dots, x_{j_n}

$$\Pr(X_1 = x_{j_1}, \dots, X_n = x_{j_n}) = \Pr(X_1 = x_{j_1}) \dots \Pr(X_n = x_{j_n})$$

Mathematical Expectation, Moments, and Other Properties of Distributions.—For many probability and statistical studies, the knowledge or determination of the full distribution is unnecessary or redundant; it is enough to know a few of its properties. Probably the most commonly used property is the mathematical expectation or mean (average); for the distribution already considered the formula for the expectation of the random variable X is

$$E(X) = x_1f(x_1) + x_2f(x_2) + \dots + x_if(x_i) + \dots$$

If there is an infinite number of values x_j , the distribution has finite expectation only if the series on the right converges absolutely; that is, only if the sum $\sum |x_j|f(x_j)$, where $|x_j|$ is the absolute value of x_j , converges. Otherwise, random variable X is said to have no finite expectation. More generally the k th moment about the origin is defined by

$$m_k = E(X^k) = \sum x_j^k f(x_j), \quad k = 0, 1, 2, \dots$$

while the k th moment about the mean has the formula

$$M_k = E(X - E(X))^k = \sum [x_j - E(X)]^k f(x_j), \quad k = 0, 1, 2, \dots$$

The second moment about the mean ($k = 2$) is called the variance, which is the square of the standard deviation (this is a definition of the latter). Another kind of moment of frequent use is the binomial moment; the k th binomial moment is given by

$$B_k = E\left[\binom{X}{k}\right] = \sum \binom{x_j}{k} f(x_j), \quad k = 0, 1, 2, \dots$$

in the notation for binomial coefficients used before. Existence conditions for all of these are similar to those for the mean.

Just as the probability distribution is considered as a single entity in a probability-generating function, the moments can be collected together in moment-generating functions, which indeed are related to the former. These relations, for probability distributions with all x_j non-negative integers, are

$$\begin{aligned} m(t) &= m_0 + m_1t + \dots + m_k t^k / k! + \dots = P(e^t) \\ M(t) &= M_0 + M_1t + \dots + M_k t^k / k! + \dots = \exp(-tm_1)P(e^t) \\ B(t) &= B_0 + B_1t + \dots + B_k t^k + \dots = P(1+t) \end{aligned}$$

Note that $m_0 = M_0 = B_0 = 1$, $M_1 = 0$, $m_1 = B_1$. Note also that the first two differ from the last, which like $P(t)$ is an ordinary generating function, in that the general term contains $t^k/k!$ rather than t^k ; because of this similarity to the exponential function, they are called exponential-generating functions. If $P(t)$ is written as

$$P(t) = p_0 + p_1t + \dots + p_k t^k + \dots$$

($p_k = f(x_k)$, $x_k = k$; $p_k = 0$, otherwise), then the equation $B(t-1) = P(t)$ is equivalent to the following expression for probabilities in terms of binomial moments

$$p_k = \sum_{j=k}^{\infty} (-1)^{j+k} \binom{j}{k} B_j$$

This is a useful formula when the binomial moments can be determined more easily than the probabilities. Of course the formulas above also supply interrelations of the three kinds of moments. Of these it is sufficient to note that

$$m_2 = 2B_2 + B_1, \quad M_2 = 2B_2 + B_1 - B_1^2 = m_2 - m_1^2$$

Finally notice that if X_1, X_2, \dots, X_n are random variables with finite means, then the mean of the sum is the sum of the means, that is

$$E(X_1 + X_2 + \dots + X_n) = E(X_1) + E(X_2) + \dots + E(X_n)$$

If these variables are mutually independent and the variance of X_k is σ_k^2 , then

$$\text{Var}(X_1 + X_2 + \dots + X_n) = \sigma_1^2 + \sigma_2^2 + \dots + \sigma_n^2$$

Also, if X_1, X_2, \dots, X_n are independent random variables with generating functions $P_1(t), P_2(t), \dots, P_n(t)$, the generating function $P(t; n)$ of the sum $X_1 + X_2 + \dots + X_n$ is given by

$$P(t; n) = P_1(t)P_2(t) \dots P_n(t)$$

This formula is especially useful when all random variables have the same distribution and hence the same generating function, say $P(t)$, so that

$$P(t; n) = [P(t)]^n$$

Important Distributions and Their Applications.—Binomial Distribution.—Consider a succession of n independent tosses of a coin with probability p for head, $q = 1 - p$ for tail; that is, what are called Bernoulli trials, after Jakob Bernoulli (1654–1705). The generating function for a single toss is $q + pt$, and by the formula just above, the generating function for n independent tosses is $(q + pt)^n$. By the binomial theorem

$$(q + pt)^n = \sum_{k=0}^n \binom{n}{k} p^k q^{n-k}$$

Hence the binomial distribution may be written as $\{b(k; n, p)\}$, $k = 0, 1, \dots, n$ where

$$b(k; n, p) = \binom{n}{k} p^k q^{n-k}$$

For $n = 2$, as already noticed in the coin tossing example, $b(0; 2, p) = q^2$, $b(1; 2, p) = 2pq$, $b(2; 2, p) = p^2$; for $n = 3$, the distribution is summarized in the table

k	0	1	2	3
$b(k; 3, p)$	q^3	$3q^2p$	$3qp^2$	p^3

The mean for a single toss is $q \cdot 0 + p \cdot 1 = p$; hence the mean for n tosses is np . The binomial moment generating function $B(t; n, p)$ is given by

$$B(t; n, p) = [q + p(1+t)]^n = (1+pt)^n$$

$$= \sum_{k=0}^n \binom{n}{k} p^k t^k$$

Hence the k th binomial moment, say $B_k(n, p)$, is given by

$$B_k(n, p) = \binom{n}{k} p^k, \quad k = 0, 1, \dots, n$$

and the variance M_2 is accordingly

$$V(n, p) = M_2(n, p) = 2B_2(n, p) + B_1(n, p) - B_1^2(n, p) = npq$$

Since all binomial moments are known, so are all ordinary and

central moments, but higher moments are so rarely needed as not to deserve space here. It should be mentioned that the value of k , say m , at which $b(k; n, p)$ reaches its maximum value is given by the inequality $(n+1)p - 1 < m \leq (n+1)p$.

Let the reader be bemused by the simplicity of coin tossing into regarding the binomial distribution as a mere mathematical amusement, it may be well to mention two applications:

Given the simplified case of n telephone lines from a central office, each line to a single customer. Suppose that during the busy hour each customer makes one 2-minute call "at random"; more precisely, suppose the probability that he is using his line at any particular time in the busy hour is $1/30$. Also suppose customers call independently. Then the probability that k lines are busy simultaneously is the binomial $b(k; n, 1/30)$, a result used in many telephone engineering studies.

In a second application (simplified) suppose there are n power wires supplied by a single electric generator. Each wire runs to a device that uses one ampere of current in a 10-minute interval at random in the busy hour, or at any particular time with probability $1/6$. Then the probability that the generator will supply k amperes to the lines is $b(k; n, 1/6)$.

Poisson Distribution.—Though the Poisson distribution is interesting in its own right, it first came to attention as a limit of the binomial distribution, with n increasing, p decreasing, but $np = \lambda$, a fixed number. For this reason it has been called "the law of small numbers," or the "law of rare events," which are now regarded as misnomers. If the binomial moment-generating function of the binomial distribution is rewritten

$$B(t; n, p) = \left(1 + \frac{\lambda t}{n}\right)^n, \quad \lambda = np$$

then it may be expected from the limit formula for the familiar number e that, as n increases,

$$\lim B(t; n, p) = B(t; \lambda) = e^{\lambda t} = \exp(\lambda t)$$

with $B(t; \lambda)$ the binomial moment-generating function for the Poisson distribution, and

$$\exp(x) = 1 + x + \frac{x^2}{2} + \dots + \frac{x^n}{n!} + \dots$$

This turns out to be true and the corresponding probability generating function is

$$P(t; \lambda) = B(t-1; \lambda) = \exp(\lambda t - \lambda) = \sum_{k=0}^{\infty} e^{-\lambda} \frac{\lambda^k}{k!} t^k$$

The Poisson distribution is $\{p_0(\lambda), p_1(\lambda), \dots, p_k(\lambda), \dots\}$ with

$$p_k(\lambda) = e^{-\lambda} \lambda^k / k!$$

which is an approximation to $b(k; n, p)$ as n increases, p decreases, while $np = \lambda$. The k th binomial moment is $B_k(\lambda) = \lambda^k / k!$, so the mean is λ and so is the variance.

Negative Binomial Distribution.—Consider, as in the example on coin tossing, the number of tosses up to first appearance of head, in an infinite sequence of tosses. If this number is k , there must be k successive tails followed by a head; the probability of this event is $q^k p$. The corresponding generating function is

$$G(t) = p \sum_{k=0}^{\infty} q^k t^k = p(1-qt)^{-1}$$

The symbol G in the generating function is a reminder that the probability distribution is the geometric distribution. Consider now the number of tosses up to the r th appearance of head. Noting that the numbers of tails between successive appearances of head all have the same distribution as the number up to the first, this is an example of the sum of r random variables each with the same geometric distribution, and

$$G(t; r) = [G(t)]^r = p^r (1-qt)^{-r}$$

If

$$G(t; r) = \sum_{k=0}^{\infty} g(k; r, p) t^k$$

then, by the binomial theorem

$$g(k; r, p) = \binom{-r}{k} p^r (-q)^k, \quad k = 0, 1, 2, \dots$$

$$= \binom{r+k-1}{k} p^r q^k$$

Note that $g(k; r, p)$ is the probability that the r th appearance of head is at trial $r+k$.

When r is an integer, the distribution is called the Pascal distribution (after Blaise Pascal [1623-1662], commonly regarded as a co-founder with Pierre de Fermat of the theory of mathematical probability); when r is a real number, not necessarily integral, it yields what is called the negative binomial distribution, because r appears with negative sign in the first form of $g(k; r, p)$.

The binomial moment-generating function is

$$B(t; r, p) = p^r (1 - q + qt)^{-r} = (1 - q/p)^{-r}$$

and so the k th binomial moment is

$$B_k(r, p) = \binom{-r}{k} \left(-\frac{q}{p}\right)^k = \binom{r+k-1}{k} \left(\frac{q}{p}\right)^k$$

The mean is rq/p and the variance is rq/p^2 .

Normal Distribution.—The function defined by

$$\phi(x) = \frac{1}{\sqrt{2\pi}} \exp(-\frac{1}{2}x^2)$$

is called the normal density function; its integral

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x \exp(-\frac{1}{2}y^2) dy$$

is called the normal distribution function. The term distribution function is used as in a previous section. The graph of $\phi(x)$ is the familiar bell-shaped curve with maximum at $x=0$ where $\phi(0) = (2\pi)^{-1/2} \approx 0.399$. The area under the curve is unity, as required by $\Phi(\infty) = 1$. The mean is zero (the curve is symmetrical) and the variance is 1. For arbitrary mean m and variance σ^2 , a change of scale is required; the normal density function becomes $\sigma^{-1}\phi[(x-m)\sigma^{-1}]$, which is shown as fig. 3, and the distribution function $\Phi[(x-m)\sigma^{-1}]$. Note that $\Phi(-x) = 1 - \Phi(x)$. The value of x such that $\Phi(x) - \Phi(-x) = 0.5$ is $x = 0.6745$; hence 0.6745σ is called in statistics (*q.v.*) the probable error. Also $\Phi(2) - \Phi(-2) = 0.9545$, and the points $m \pm 2\sigma$ are called the 95.5% points; $\Phi(3) - \Phi(-3) = 0.9973$, corresponding to points $m \pm 3\sigma$, usually includes all the curve of interest in statistical work. The ordinary moment-generating function of the normal distribution with mean m and variance σ^2 is defined by

$$m(t) = 1 + mt + m^2 t^2/2! + \dots + m^k t^k/k! + \dots$$

$$= \int_{-\infty}^{\infty} e^{tx} \phi\left(\frac{x-m}{\sigma}\right) \frac{dx}{\sigma} = \exp(mt + \sigma^2 t^2/2)$$

Hence the central moment-generating function is

$$M(t) = \exp(-mt)m(t) = \exp(\sigma^2 t^2/2)$$

All odd central moments are zero, and

$$M_{2k} = \frac{(2k)!}{2^k k!} \sigma^{2k} = 1 \cdot 3 \cdot 5 \dots (2k-1) \sigma^{2k}$$

As n increases, the binomial distribution $\{b(k; n, p), k = 0, 1, \dots, n\}$ resembles the normal distribution more and more closely. Indeed under conditions spelled out in the De Moivre-Laplace limit theorem (for which the reader may consult the treatise by Feller in the *Bibliography*), the normal distribution is the limit of the binomial distribution.

Central Limit Theorem; Law of Large Numbers.—The Central Limit Theorem (named by George Pólya in 1920) is an outstanding result in probability theory (*see* ERRORS, THEORY OF). It explains the importance and common empirical appearance of the normal distribution, and is stated as follows:

Let $\{X_k\}$ be a sequence of mutually independent random vari-

ables with a common distribution, which has finite mean m and variance σ^2 . Let $S_n = X_1 + \dots + X_n$. Then for every fixed β

$$\Pr \left\{ \frac{S_n - nm}{\sigma \sqrt{n}} < \beta \right\} \rightarrow \Phi(\beta)$$

The arrow means approaches (for increasing n) and $\Phi(\beta)$ is the normal distribution function. Note that the mean of S_n is nm and the variance of S_n is $n\sigma^2$. The variable

$$S_n^* = [S_n - E(S_n)] / \sqrt{V(S_n)}$$

with $E(S_n)$ the mean and $V(S_n)$ the variance of S_n , is called the normalized form of S_n .

A related limit theorem is the Law of Large Numbers, stated as: Let $\{X_k\}$ be a sequence of mutually independent random variables with a common distribution that has a finite mean m . Then for every $\epsilon > 0$ as $n \rightarrow \infty$

$$\Pr \{ |S_n/n - m| > \epsilon \} \rightarrow 0$$

In ordinary language, this says that the probability that the average S_n/n will differ from m by less than an arbitrarily small positive number ϵ , tends to one. The law furnishes a justification for association of probabilities with frequencies for repeated trials.

While the Central Limit Theorem is a generalization of the De Moivre-Laplace theorem (referred to before as showing that the binomial distribution tends to the normal) it is by no means the most general statement of its kind. For instance its conclusion holds when the variables of the sequence do not necessarily have the same distribution, but the conditions for the validity of the theorem in this case are not easy to state in ordinary language and in mathematical language would probably be baffling to some.

It should be noted that if X_1 is a random variable with a normal distribution of mean m_1 and variance σ_1^2 and X_2 is independent and similar but with mean m_2 , variance σ_2^2 , then the sum $S_2 = X_1 + X_2$ is a variable with a normal distribution of mean $m_1 + m_2$, variance $\sigma_1^2 + \sigma_2^2$. Because of this property, the normal distribution is said to be self-reproductive. The Poisson distribution is also self-reproductive, but the binomial and negative binomial distributions are not.

Two or More Random Variables.—A compound event usually needs several random variables for complete description. Consider a compound of two events, say, the outcome of the tossing of two dice numbered 1 and 2; the corresponding random variables are X and Y . Any outcome is associated with a joint probability, say $p_{ij} = \Pr(X=i, Y=j)$ and the totality of outcomes with a joint probability distribution $\{p_{ij}\}$ where i takes on the values x_1, x_2, \dots of X , and j has the values y_1, y_2, \dots of Y . Similarly the joint distribution function is

$$F(x, y) = \Pr(X \leq x, Y \leq y) = \sum p_{ij}$$

where the sum is taken over all values of i not greater than x and all values of j not greater than y . When y is greater than the largest value of Y (or infinity), the joint distribution function becomes a function of x only and is called the marginal distribution function of X . The marginal distribution of Y is defined similarly. Joint moments also are needed; for moments about the origin these are given by

$$m_{rs} = E(X^r Y^s) = \sum_{i,j} i^r j^s p_{ij}, \quad r, s = 0, 1, 2, \dots$$

while joint central and binomial moments are defined by

$$M_{rs} = E[(X - E(X))^r (Y - E(Y))^s]$$

$$= \sum_{i,j} (i - E(X))^r (j - E(Y))^s p_{ij}$$

$$B_{rs} = E \left[\binom{X}{r} \binom{Y}{s} \right] = \sum_{i,j} \binom{i}{r} \binom{j}{s} p_{ij}$$

Of course $E(X) = m_{10}$ and $E(Y) = m_{01}$. The central moment M_{11} is called the covariance and is given by

$$\text{Cov}(X, Y) = E(XY) - E(X)E(Y) = m_{11} - m_{10}m_{01}$$

If X and Y are independent $\text{Cov}(X, Y) = 0$. The ratio of the

covariance of X and Y to the product of their standard deviations is called their correlation coefficient and is usually written ρ_{xy} . If X_1, X_2, \dots, X_n are random variables with finite variances $\sigma_1^2, \sigma_2^2, \dots, \sigma_n^2$, then

$$\text{Var}(X_1 + \dots + X_n) = \sigma_1^2 + \dots + \sigma_n^2 + 2 \sum_{i < j} \text{Cov}(X_i, X_j)$$

(the sum extending over all $n(n-1)/2$ pairs (X_i, X_j) with $i < j$). To fix ideas it may be helpful to consider the following simple example.

Correlated Tosses of Two Coins.—Suppose coins are tossed by some device that assures nonindependence, so that sample space points TT, TH, HT, HH have respective probabilities $p_{00}, p_{01}, p_{10}, p_{11}$ (with a sum of unity). The joint probability-generating function is

$$P(t, u) = p_{00} + p_{01}u + p_{10}t + p_{11}tu$$

and the binomial moment-generating function is

$$B(t, u) = 1 + (p_{01} + p_{11})u + (p_{10} + p_{11})t + p_{11}tu$$

The moments are

$$m_{00} = B_{00} = 1; \quad m_{10} = B_{10} = p_{10} + p_{11};$$

$$m_{11} = B_{11} = p_{11}; \quad m_{01} = B_{01} = p_{01} + p_{11}$$

and

$$M_{11} = m_{11} - m_{10}m_{01} = p_{11} - (p_{10} + p_{11})(p_{01} + p_{11})$$

$$= p_{11}(1 - p_{10} - p_{01} - p_{11}) - p_{10}p_{01} = p_{11}p_{00} - p_{10}p_{01}$$

Multinomial Distribution.—This important multivariable distribution is a generalization of the binomial distribution. Instead of two outcomes on a single trial, there are k (as with a k -faced die) and the i th outcome has probability p_i . Associating a variable t_i with the i th outcome, the probability-generating function is

$$P(t_1, \dots, t_k) = (p_1 t_1 + \dots + p_k t_k)^n$$

where the general term is $[n; x_1, \dots, x_k] (p_1 t_1)^{x_1} \dots (p_k t_k)^{x_k}$, with $[n; x_1, \dots, x_k]$ the multinomial coefficient $n! / x_1! \dots x_k!$, and $x_1 + \dots + x_k = n$.

Multivariable Normal Distribution.—This distribution becomes complicated if stated in more than two variables, but for two variables with means m_1, m_2 , variances σ_1^2, σ_2^2 , and correlation coefficient ρ_{12} , the two-variable density function may be written as the following equation:

$$f(x, y) = \frac{1}{2\pi\sigma_1\sigma_2\sqrt{1-\rho_{12}^2}} \exp -\frac{1}{2}q(x, y)$$

where

$$q(x, y) = \frac{1}{1-\rho_{12}^2} \left[\frac{(x-m_1)^2}{\sigma_1^2} + \frac{(y-m_2)^2}{\sigma_2^2} - 2\rho_{12} \frac{(x-m_1)(y-m_2)}{\sigma_1\sigma_2} \right]$$

Kolmogorov System of Axioms.—The simplicity of the Kolmogorov system of axioms may be surprising. Let E be a collection of elements $\{E_1, E_2, \dots\}$ called elementary events and F a set of subsets of E called random events. The axioms for a finite set E are:

- I. F is a field of sets
- II. F contains set E
- III. A non-negative real number $P(A)$, called the probability of A , is assigned to each set A in F
- IV. $P(E)$ equals 1
- V. If A and B have no element in common, the number assigned to their union is $P(A+B) = P(A) + P(B)$

Axiom I needs the following explanation. A system of sets is called a field (see FIELDS) if the union, product, and difference of any two sets is a set in the field; the product (i.e., intersection) of two sets is the set of elements common to both; the difference of two sets A and B , written $A-B$, is the set of elements of A that are not in B (the difference $E-A$ is the complement of A). For an infinite set E , the preceding axioms apply, and an axiom of continuity must be added:

VI. For a decreasing sequence of elements of F , that is, $A_1 \supset A_2 \supset \dots \supset A_n \supset \dots$ for which $A_1 A_2 \dots A_n \dots = 0$ the following limit equation holds:

$$\lim_{n \rightarrow \infty} P(A_n) = 0$$

The symbol \supset of set inclusion in $A_1 \supset A_2$, for example, means that every element of set A_2 is an element of set A_1 .

(JO. RI.)

PROBATE, the judicial proceedings by which it is determined whether or not a paper purporting to be the last will of a deceased person is his legally valid last will. What appears to be a valid will may not be so; it may have been forged, or not executed in the way required by law, or the testator may have signed it while mentally incompetent or under duress, or he may subsequently have revoked it. If the document is held to be genuine and valid, it is admitted to probate; otherwise its admission is refused. Until it has been so admitted it cannot be used for any legal purposes; in particular, the person nominated as executor cannot function, and the court must appoint an administrator of the estate.

The idea that the genuineness and validity of a will should be investigated and determined in special proceedings was developed in England by the ecclesiastical courts, which in the Middle Ages had acquired jurisdiction over succession to personal property. No such idea had been worked out by the secular courts, which had jurisdiction over the descent of real property. In America, secular courts were set up to deal with probate matters, and in the 19th century their jurisdiction was extended to cover the problem of the validity of a will with respect to real property. The same step was taken in England in 1897, after jurisdiction had been transferred in 1857 from the ecclesiastical to the secular courts.

Under the rules developed in the ecclesiastical courts and continued in the English secular courts, probate can be granted simply upon the presentation of an instrument (document) presenting the outward appearance of a will properly executed. Such probate "in the common form" was revocable, however, if within 30 years doubts were raised as to the validity of the instrument. In that case, the person interested in having it admitted to probate had to prove it "in the solemn form." These more elaborate proceedings were also required if an interested person had entered a caveat (asked to have his objections heard) before the probate had been granted. Probate in the solemn form is a regular judicial proceeding in which the facts needed to establish the validity of the instrument must be proved, ordinarily through testimony by witnesses.

In England, probate jurisdiction ordinarily rests with the Probate, Divorce, and Admiralty Division of the High Court, which normally acts through the Principal Registry in London or through its local district registries. Where the gross value of the deceased's property does not exceed £500, application for probate may be made through the local officers of the Board of Custom and Excise. The documents admitted to probate are deposited in the Principal Registry in Somerset House, London, where they are open to public inspection. A certified copy is issued to the executor. When probate is granted, estate duty is payable on the gross value of the personal estate and the real estate owned in England. (See ESTATE AND INHERITANCE TAXES.)

In Scots law, proceedings essentially corresponding to probate are called confirmation and are carried out in the Sheriff's Court.

The English pattern is also that of the other common-law parts of the Commonwealth and, basically, also that of the United States. Under the pattern prevailing in most states in the U.S., the document purporting to be a will is admitted to probate in a special court, usually called the Probate Court (Surrogate's Court in New

York, Orphans' Court in New Jersey and Pennsylvania). Proceedings require little proof, but occasionally allow the adjudication of a limited range of objections. But any interested party may have the probate revoked if he prevails in a will contest; this must be raised, usually in a court higher than the probate court, within a short period fixed by statute.

In most states the courts acting in probate matters also supervise the administration and distribution of a deceased's estate by an executor or administrator; in addition, they have jurisdiction over the guardianship of infants and the conservation of the estates of mentally incompetent persons. In Pennsylvania certain probate functions are carried on by an official called prothonotary. In some states, probate matters are handled by the courts of first instance—in California, for example, by the district courts.

Matters of probate belong exclusively to the courts of the several states, federal courts having no jurisdiction. Probate must be obtained in the state of which the deceased was a resident at the time of his death; in addition, ancillary probate must be obtained in every other state in which real property is located and, under certain circumstances, also in every other state in which the deceased had a bank account or other personal property. See also **WILL**.

Marshall, *Ancient Courts of Probate* (1895). (M. RN.)

PROBATION is a correctional method under which the sentences of selected offenders may be conditionally suspended upon promise of good behaviour and agreement to accept supervision and abide by specified requirements including, usually, reporting to a probation officer or to the court at regular intervals. As distinct from parole (*q.v.*), which involves conditional release from confinement after part of a sentence has already been served, probation permits the offender to retain his freedom and continue to meet his personal, family, and community responsibilities.

Probation Procedure.—*Adult.*—The adult probation process begins with a presentence investigation of the offender after his guilt has been established. The investigation is made by the probation officer and is usually ordered by the court whenever an offender is legally eligible for probation. Statutes commonly exclude from consideration persons convicted of serious offenses (*e.g.*, armed robbery, murder) or those previously convicted of other offenses. The social investigation serves, first, to help the court determine whether the offender is suitable for probation, and, second, to outline a plan of corrective treatment. It is primarily concerned with the offender as an individual, his personality and background, education and employment, and his family and social environment. This information is incorporated and evaluated in a confidential report to the court.

When probation is ordered by the court, the offender is placed under the supervision of a probation officer, or a person appointed by the court, and under conditions specified in the probation order. Typically these require that the probationer conduct himself properly; that he maintain his local residence; report regularly to his probation officer; support his family; pay restitution; avoid criminal associations and disreputable places; and abstain from drinking. In addition he may be ordered to obtain medical or psychiatric care. The status of a probationer may carry other restrictions as to civil rights, freedom to act in certain matters without approval, and access to social or employing organizations.

The duration of probation set by the court generally is limited to some maximum term. Early discharge by the court in recognition of good conduct is a common practice.

The probation officer's fundamental task is to help the probationer become a more responsible and better-adjusted person. The essence of probation is good casework, not mere supervision; and its aim is individual rehabilitation, not the relief of crowded institutions. Individual counseling and available social, occupational, educational, and mental health resources are employed to help the probationer resolve specific problems, conflicts, and attitudes that led to his criminal or delinquent behaviour. As a rep-

resentative of the court, the probation officer must also enforce the conditions set by the court and be watchful regarding further antisocial activities on the part of the probationer.

If the probationer violates the terms of his probation or commits a further offense during the probation period, he may be brought back before the court for revision or revocation of the original order of probation and may be given some other sentence for the original offence. When the probationer completes his period of probation successfully he is discharged from further obligations to the court. Studies made in several countries show that 70% to 80% of all probationers successfully fulfill the terms of probation and are discharged. Limited evidence suggests that the proportion of former probationers convicted of subsequent offenses is small, probably less than three in ten.

Juvenile.—Probation work among children differs materially from that among adults and is of even greater importance. Juvenile court hearings are characterized by their informal proceedings and discretionary protective treatment. In some jurisdictions the probation officer's investigation is completed and the report submitted prior to the court hearing. Consequently, information in the report may significantly influence the determination of delinquency as well as the disposition of the case. For probation to be effective it is essential that a child offender after being adjudged a ward of the court be given very careful supervision; that his mental, physical, and psychological characteristics and his social situation receive the closest study; and that his probation officer establish and maintain close personal relationships with the child and his home and keep in close touch with his school or work and his free-time activities. Generally, for children and youth under juvenile court jurisdiction, the period of probation is indefinite and dependent upon the individual's attitude and adjustment. (See **CHILDREN'S COURT**; **JUVENILE DELINQUENCY**.)

Origin and Development.—Probation evolved from Anglo-American judicial practices devised to avoid automatic application of harsh penalties prescribed by the statutory law. These practices originated in the early 1800s in response to humanitarian concern over the harmful effects of imprisonment on the young or first offender. Enlightened English magistrates in such cases imposed only a token sentence, remanding the offender to the custody of his parents or master for more careful supervision. This was a final disposition, however; the court had no power to enforce its order. A remedy was found in the recognizance (*q.v.*), an old measure of preventive justice. Conditional upon his good behaviour, an offender could be released on his acknowledgment of obligation until some later date set by the court for final action. He was often required to post bond or deposit bail to guarantee reappearance.

John Augustus, a Boston bootmaker, initiated the practice he called "probation." In 1841, through his interest in the temperance cause, he appeared in court and posted bail for a man charged with drunkenness. Successful in helping the man get reestablished, he proceeded to assist hundreds of men, women, and children charged with a variety of offenses.

The voluntary work of Augustus and his successors led the Massachusetts legislature to authorize in 1878 the appointment of a paid probation officer to serve the Criminal Court of Boston. Subsequent legislation made probation services mandatory in most Massachusetts courts. Other states were slow to follow the example until the turn of the century, when the children's court (*q.v.*) movement began to sweep the United States. In England the efforts of temperance volunteers in the police courts paralleled the development of probation in the United States. Beginning in 1879, a series of pertinent statutes was enacted culminating in the Probation of Offenders Act of 1907, which established official, salaried probation officers in the criminal courts of the United Kingdom. British criminal courts have general jurisdiction over juveniles as well as adults. In 1948 the Criminal Justice Act added significant improvements in the legal and practical application of the probation system. (See also **BORSTAL SYSTEM**.)

On the continent of Europe, progressive elements had also long supported the mitigation of punishment for juvenile and first offenders. Europeans were primarily interested in a substitute for

short-term imprisonment rather than extended probation services. They adopted a procedure whereby sentence was imposed but with provision for suspending execution of the punishment subject to the offender's good behaviour. The measure was considered to be preventive because of the deterrent effect of imminent punishment. First authorized by Belgian law in 1888, the conditional sentence was shortly adopted by France and eventually spread to nearly every European state.

The facilities of the United Nations permitted a comparative view of leading nations with respect to statutory authorization for and administration of probation services in the second half of the 20th century. In the United States and in Canada, the United Kingdom, and other nations of the British Commonwealth, legal provision for probation was nearly universal. Administration of services was predominantly local and subject to close judicial control. The established pattern of service was characterized by public employment of full-time probation officers, but part-time and ex-officio services were relied upon in some localities of the U.S. and in some nations of the Commonwealth.

Of 16 continental European countries, virtually all provided juveniles with services legally and practically comparable to probation. The conditional suspension of sentence for adults was authorized by law in all save one of these countries. In more than half, a supplemental order for personal supervision was legally permitted, but this option was not much employed by the courts. Considerable experimentation was going on with the aim of adapting the probation method to the system of criminal jurisprudence, notably in France, the Federal Republic of Germany, the Netherlands, and the Scandinavian countries.

Most continental European countries have delegated the personal supervision of probationers to social welfare organizations dependent on volunteer services. A general trend toward professional probation services has been exemplified in the Belgian, French, Dutch, and Swedish systems. There, trained probation consultants are responsible for indoctrinating volunteer agents, supervising their work, and in many cases giving direct services to probationers. The move toward professionalization has been accompanied by increased central government responsibility for coordination, regulation, or administration of probation services.

Those metropolitan areas in Latin America, Asia, and Africa where the juvenile court philosophy has been embraced offer probation services largely limited to juveniles. Voluntary welfare organizations usually have provided the necessary supervision and treatment services.

Authorities concerned with the legal and sociological aspects of law enforcement generally agree that probation, rather than institutional confinement, is a more effective and far less expensive program for the rehabilitation of the majority of offenders. By the middle of the 20th century its full potential for successful application had not been realized, even in those countries where it was best developed. Relatively few areas in the world adhered strictly to all of the principles that were considered essential to the proper administration of probation: (1) careful selection of cases amenable to supervision, with consideration given on the basis of the offender's likelihood to improve under treatment, rather than the seriousness of his offense; (2) suspension of sentence for persons so selected; (3) supervision by professionally trained personnel; (4) release of the probationer at the end of a specified period set by the court, provided behaviour has been satisfactory, or revocation of probation if he has committed a new crime or failed to comply with the conditions of his probation.

Among organizations promoting the growth and extension of the probation system throughout the world are the Economic and Social Council of the United Nations; the National Council on Crime and Delinquency, New York; the American Correctional Association, Washington, D.C.; and the National Association of Probation Officers, London.

PROBOLINGGO, a port of East Java Province, Indonesia, and headquarters of a district of the same name, is situated at the south of the Madura Strait, about 60 mi. (97 km.) SE of Surabaya. Pop. (1961) 68,838, including many Chinese. There is a good harbour for small ships, and the fishing industry is important. Cottage industries include pottery and the manufacture of sarongs. The town is on the rail and road routes from Surabaya to Banjuwangi. The surrounding district grows rice, maize (corn), sugar, and some coffee; its mangoes are renowned for their excellence.

PROBOSCIDEA, an order of mammals that includes the present-day elephants and their fossil relatives, the mastodonts and mammoths. The proboscidean line can be traced back to a tapirlike animal of Upper Eocene Age (about 50,000,000 years ago). The descendants of this modest-sized plant eater became progressively larger during succeeding epochs: the mastodonts (or mastodons), so called because their cheek teeth had teatlike cusps, preceded the elephants proper, including the mammoths.

The body systems of proboscideans generally are those common to other placental mammals (see **MAMMAL**), and the present article is concerned mainly with those special features that characterize the Proboscidea and set it apart from other mammalian orders. A discussion of living elephants precedes a treatment of the phylogenetic relationships of earlier proboscideans.

GENERAL

Elephants are the largest recent land mammals, and may be the largest ever to have existed. They are among the longest-lived mammals, approaching the age of a man. They live in herds now restricted to Africa and tropical Asia. The evolution and spread of the order, the oldest members of which are known from remains in northeastern Egypt, is greatly complicated by the existence of many side branches, some abortive, which migrated into Asia, thence to Europe and, across what is now the Bering Straits, into North America, and, near the close of the Ice Age, even into South America.

Common animals of the Ice Age were the woolly mammoths of Europe—whose frozen carcasses have been uncovered in the ice-bound tundra of Siberia—and, in America, the last of the mastodonts.

The name Proboscidea refers to the elongated snout or proboscis, the trunk; the evolutionary development of this most remarkable feature of living elephants is indicated by a series of fossil skulls. The dentition is also unusual, in many cases involving reduction of the number of teeth in use at one time with corresponding increased complexity of the teeth that gradually erupted during a long period of life. The molars became very effective grinders of plant food; the specialized front teeth were often modified into tusks. See **ELEPHANT** for information of popular interest.

CHARACTERISTIC STRUCTURES

The massive body is supported by pillarlike limbs; the large head is joined to the body by a very short neck. Hair, conspicuous as a body covering in the young, is reduced in the adult to a patch on the forehead and a tuft on the tail.

Soft Parts.—The trunk is a long, flexible, muscular organ that can be turned freely in every direction. It is provided with one or two fingerlike processes at its tip, which can be used to handle articles as small as a penny. Being prehensile, the trunk can be wrapped around large objects; it is capable of considerable precision of movement and is used in feeding.

The trunk represents the whole anterior part of the face, i.e., the nose and also the upper lips, the strip of skin along its ventral surface being essentially a part of the palate. The two nostrils lie at the extremity of the trunk and lead into great canals that perforate the whole of that organ, opening into olfactory chambers

at its base. The mouth is short, placed below the trunk, and provided with thick fleshy lower lips that meet anteriorly to form a short spout. The eye is small, laterally directed, and provided with a pair of eyelids often bearing stiff eyelashes. The earflaps are large, largest in certain races of the African elephants. They are usually carried close to the side of the neck but can be erected so as to stand out perhaps a yard from the side of the head.

The anatomy of the soft parts of the elephant presents few features of special interest, except those that result from the modification of the nose and upper lips into the trunk. The animal is peculiar in that there is no pleural cavity. The female bears two teats placed forward just between and behind the forelegs. The fact that the testes are abdominal, the uterus bicornuate, and the placenta zonary and deciduate is of importance because similar conditions occur in the Sirenia (sea cows), which may have sprung from an early Proboscidean stock.

Skull.—The skeleton of an elephant is as peculiar and characteristic as its external appearance. The skull is very short from back to front, deep, and built up of spongy bone full of air spaces. Within the great mass of bone lies the brain cavity; the olfactory chambers form great perforations that, with the nasopharyngeal

SKULL AND JAWS OF EXTINCT PROBOSCIDEANS

(A) Lower jaws of *Amebelodon*, from the Pliocene of North America; (B) *Palaeomastodon*; (C) *Deinotherium*; (D) *Mammuthus*, the woolly mammoth; (E) *Moeritherium*, from the Upper Eocene and Lower Oligocene of Egypt

ducts, penetrate obliquely through the skull and unite posteriorly. The skull of the newborn elephant increases greatly and disproportionately in size, but the brain undergoes much less expansion. Thus during the period of growth of the animal the external surface of the skull, by the development of great air spaces in its middle layer, becomes more and more widely separated from the layer of hard bone that surrounds the brain. The bony layers that separate these air spaces run radially so as to buttress the external surface. The great size of the adult skull is necessary in order to give adequate areas for the attachment of the immense neck muscles, which support and move the very heavy trunk and tusks and take the great strains produced when these structures are used in digging up and tearing down trees.

The jawbones of the elephant and the whole structure of its palate are modified so as to receive, and afford adequate support to, the tusks and cheek teeth. The bony nostrils lie very high up and are overhung by very small nasal bones to which some of the muscles of the base of the trunk are attached. This attachment is brought as far back as possible in order to increase the range of action of the trunk.

Teeth.—The dentition of an adult elephant typically consists

of a single pair of exaggerated incisors, the tusks, and either one or two molars on each side of the upper and lower jaws. The molars are built up of a series of vertical plates, each composed of a core of dentine surrounded by a layer of enamel; the individual plates, joined at their bases, are held together and supported by an infilling of cement. In the elephant the milk incisors, little teeth about two inches in length, are shed and replaced by the permanent tusks, but the milk molars, instead of being pushed out by a permanent premolar that develops underneath them, replace one another from behind as follows.

The new tooth is developed deep down in the posterior part of the jaw and travels obliquely forward and toward the mouth, so that more and more of it erupts from the gum as the preceding tooth is worn down to its root, until finally the latter is shed and its successor is exposed and already partially worn. A living elephant in this way works through six teeth in each side of each jaw during its normal lifetime, wearing down a total thickness of nearly a yard of tooth over an area that increases from about $\frac{1}{2}$ sq.in. to nearly 30 sq.in. on each side of its mouth. This extraordinary dentition is unparalleled in any other animal.

Body Skeleton.—The elephant's backbone consists of a neck of 7 very short vertebrae; a dorsal region of 19 to 21 vertebrae, the anterior ones having long neural spines for the attachment of a ligament that passes forward to the back of the skull; a short lumbar region of 3 or 4 vertebrae; a sacrum composed of 4 fused vertebrae; and a caudal region of about 30 progressively smaller vertebrae extending to the tip of the tail. The ribs are of enormous length surrounding the very capacious thorax. The shoulder girdle consists of a very large triangular scapula placed vertically on each side of the thorax. The upper segment of the forelimb (humerus) is longer than the lower segment so that the elbow of an elephant lies at a point relatively only a little higher than the wrist of a horse. The radius and ulna, in the lower segment, are peculiar in that their surfaces of articulation with the carpus are nearly equal, while the upper end of the radius is relatively small and lies in front of the ulna, the two bones crossing one another as they are traced downward. The carpus of an elephant is unusual in that the bones of the two rows of which it is composed do not alternate but are superimposed on one another. (In this feature the elephants resemble the hyraxes.)

The elephant walks on the extreme tips of his fingers and toes, but the palm of the hand and the sole of the foot are swollen out into great pads of connective tissue and fat, which transmit the weight of the animal to the ground directly and so reduce the load carried by the phalanges. The elephant's pelvis is remarkable for its extraordinary width, the ilia being expanded into transversely placed sheets of bone from whose posterior surface muscles pass down to the hind leg, while their margins give attachment to the muscles of the body wall, which support the weight of the viscera within the abdominal cavity. As in the forelimb, the upper segment of the leg is considerably longer than the lower one, and in the tarsus the astragalus is flattened, as a weight-carrying adaptation, while the calcaneum is produced into a short heel directed backward and downward.

SURVEY AND RELATIONSHIPS

The Proboscidea can be divided into three suborders: Moeritherioidea and Deinotherioidea, each with one genus, and Elephantioidea, which includes the living elephants, the mammoths and the mastodons.

MOERITHERIOIDEA

The most primitive and earliest known ancestors of the elephant belong to the genus *Moeritherium* and are found in Upper Eocene deposits in northern Egypt. *Moeritherium* resembled the living tapir in its external appearance and size. The eye was placed far forward and the head was low and elongated; probably the end of the snout was slightly flexible, and it may have been produced into a short proboscis. The legs were considerably more bent than those of modern elephants but are still rather incompletely known. *Moeritherium* possessed three upper and two lower incisors, of which the second pair were enlarged, those in the upper jaw

PROBOSCIDEAN EVOLUTION

Some of the more important members of the order (drawn in proportional scale). *Moeritherium*, about 2 ft. tall, was the earliest known proboscidean. The first of the mastodonts, *Palaeomastodon*, had the beginnings of a trunk and two pairs of tusks. *Tetrabelodon* began the trend toward gigantism. *Mastodon* had the largest tusks of any proboscidean (8-10 ft.). *Amebelodon* was a proboscidean experiment with shovel-like lower tusks. *Stegodon* was the first of the true elephants. *Mammuthus*, the largest proboscidean, and *Elephas* evolved during the Ice Age.

projecting straight downward, while the lower teeth were directed forward so that their tips bit against those of the upper incisors. There was a small and very reduced canine tooth; three premolars

were present in each jaw and there is evidence that each of these vertically replaced a milk tooth. Three permanent molars lay in both upper and lower jaws, each bearing two transverse ridges.

ELEPHANTOIDEA

Mastodont Group.—The next stage, represented by *Palaeomastodon* from the Lower Oligocene of Egypt (about 40,000,000 years ago), presented a great advance over *Moeritherium*. There were several species, of which the largest was not very much smaller than a small elephant, while the smallest was little bigger than the largest *Moeritherium*. The back of the skull began to show the separation of the outer surface from the brain cavity by air spaces, a condition carried to an extreme in the living elephants. The bony nostril was shifted backward to a point in the middle of the cheek teeth, and in front of it the premaxillae formed an open channel in which lay the base of what later became the trunk. The second incisor was very much enlarged and directed forward and downward. The lower jaw was so much longer than the skull that the incisors, which lay horizontally, projected forward several inches in front of the upper jaw, and even extended beyond the tips of the upper incisors. The single "second" lower incisor was enlarged, and with its fellow formed a shovel-shaped termination to the lower jaw. The shape of this tooth was such as to show that its upper surface was worn by contact with some part of the animal, and the only explanation of its structure is that the nose, upper lip, and palate projected so far forward as to overhang the front of the lower jaw and form there a movable proboscis. The lower incisors were, however, worn all round, in a way suggesting that the animal used them for grubbing about in the ground to secure food. There were three upper premolars, each of which replaced a milk tooth, while in the lower jaw the three milk molars were replaced only by two premolars. Both upper and lower molar teeth had three transverse ridges, an advance over those of *Moeritherium*. The body of the animal was much like that of a small elephant, but the neck was longer.

In the next stage, represented by *Tetrabelodon angustidens* from the Miocene (25,000,000 years ago) of Europe, North America, Africa, and Baluchistan, appeared an animal somewhat larger than the largest *Palaeomastodon*, with a completely elephantlike body, though with a somewhat longer and more flexible neck. The skull was much more elephantlike than that of *Palaeomastodon* because of the increased bulk of the air cavities in its bones. It supported a pair of immense incisors, which, unlike the tusks of living elephants, were down turned and provided with a belt of enamel lying on the outer surface of the ivory of which they were composed. The lower jaw was even longer than in *Palaeomastodon*, nearly half its length projecting in front of the bony skull. The lower tusks were directed forward and bore a wear facet on their upper surfaces made by friction against a pad on the flexible and unsupported anterior part of the face, soon to be, if it had not already become, a true trunk. *Tetrabelodon* still possessed milk molars, which were replaced vertically by premolars, but these latter were comparatively small teeth soon displaced by the cutting of the second and third molars, which pushed their way forward from the cavity in the hinder part of the jaw in which they were formed. This process was carried so far that the adult had only two molars, the second and third, in position in each jaw. The individual teeth, though larger than those of *Palaeomastodon*, still had only three ridges, except in the case of the third molar, which had five. It seems evident that the enormously elongated jaws of *Tetrabelodon angustidens* developed as an adaptation to allow the animal, which was growing taller without a compensating increase in neck length, to reach the ground.

With the appearance of *Tetrabelodon longirostris*, the elephants came to depend on their trunks for eating and drinking. As the elongated lower jaw was thus no longer necessary, and must have interfered with the free use of the trunk, its anterior extension became very rapidly reduced in size so that it no longer extended in front of the bony upper jaw. In these animals only one milk molar was replaced by a premolar and the first two molar teeth each had four or five transverse ridges. The lower tusks were short and rounded while the upper tusks became still larger and outwardly directed. In these forms the shortening of the lower jaw allowed the trunk to fall down vertically, as it does in modern elephants, and in external appearance they must have been entirely elephantine. (See also MASTODON.)

Elephant Group.—The later mastodonts passed gradually into the elephants in Pleistocene times (1,000,000 years ago) by a still further reduction of the lower jaw, the lower tusks becoming quite small and eventually disappearing altogether; finally the front of the lower jaw became reduced to a very small downturned spout, which is retained in the living elephants. In the later forms the milk teeth were no longer replaced vertically by premolars; where they do occur they must have been pushed out almost immediately by the forward movement of the molar teeth. At the beginning of the series, the second molar tooth in either jaw had four or five ridges, separated from one another by deep valleys in which there was no cement. In an intermediate stage, *Stegodon*, the number of ridges varied from 6 to 12 in different forms and the valleys between these ridges became filled up with cement. In the true elephants the ridges were not only more numerous but much higher, and the cement formed a plate lying between them. Continuation of this process led to the most highly specialized of all elephants, *Mammuthus*, the mammoth, in which the number of ridges in the second molar may have been as great as 16, and the whole tooth was extraordinarily deep. See also MAMMOTH.

DEINOTHERIOIDEA

Of proboscidean side branches much the most striking was that represented by *Deinotherium*, which had an elephantlike body, apparently with exceptionally long limbs and a trunk. This animal was remarkable because its molar teeth throughout the whole history of the genus were very low crowned and had only two transverse ridges. The upper tusks were completely absent, while the large lower tusks were directed downward at right angles to the lower jaw. *Deinotherium* was probably of African origin and was found only in that continent and in Europe and India.

CLASSIFICATION

The following taxonomic scheme of the order Proboscidea is one generally subscribed to by mammalogists (extinct groups are preceded by an asterisk):

- * Suborder Moeritherioidea
 - * Family Moeritheriidae, *Moeritherium*
 - Suborder Elephantioidea
 - * Family Gomphotheriidae, *Gomphotherium*, *Tetrabelodon*, etc.
 - * Family Mastodontidae, *Mastodon* (mastodonts proper)
 - Family Elephantidae, **Stegodon*, **Mammuthus* (mammoth), *Loxodonta* (African elephants), *Elephas* (Asiatic elephants)
 - * Suborder Deinotherioidea
 - * Family Deinotheriidae, *Deinotherium*
- See H. F. Osborn, *Proboscidea*, 2 vol. (1936-42). (D. M. S. W.)

PROBUS (MARCUS AURELIUS PROBUS), Roman emperor A.D. 276-282, was the son of a Balkan army officer, and served with distinction in the army. He was apparently praetorian prefect in the east when his troops proclaimed him emperor in opposition to Florian (*q.v.*), who was soon killed by his own troops. Probus' reign was spent in continual frontier warfare, on the Rhine and Danube and later in the east, complicated by a series of risings in Britain, Gaul, and the east. Fourth-century writers credit him with a great interest in agriculture; he is said to have sighed for the day when men could abandon their swords for the plow, to have encouraged the vine in Gaul, Spain, and Britain, and to have been killed by troops who resented being detailed to agricultural reclamation work in the Balkans. He was succeeded by Carus.

PROBUS, MARCUS VALERIUS (fl. second half of the 1st century A.D.), Latin grammarian and literary critic, of Berytus (Beirut) in Syria. The title of his lost treatise *De inaequalitate consuetudinis* suggests that he was of the Anomalist school. His critical editions of Plautus, Terence, Lucretius, Horace and Persius, and of Virgil's *Aeneid* are also lost; but there is extant a commentary on Virgil's *Eclogues* and *Georgics* under his name. The extant part of *De notis* (probably an excerpt from a larger work), which deals with abbreviations, is printed by H. Keil, *Grammatici Latini*, vol. iv (1864); but other works ascribed to Probus in that volume are not his.

See J. Steup, *De Probis grammaticis* (1871); J. Aistermann, *De M. Valerio Probo Berytio* (1910). (R. H. Rs.)

PROCACCINI, a family of Italian painters of the Bolognese school. **ERCOLE THE ELDER** (1520?–1591?) was born in Bologna but moved to Milan, where he began a school of painting known as the Academy of the Procaccini, in which many fine painters were trained. He himself was a student of Annibale Carracci, a founder of the eclectic school of painting. His best works are in the churches of Bologna.

CAMILLO (1546–1629?), **GIULIO CESARE** (1548?–1626), and **CARLO ANTONIO** (1555–1605?), his three sons, studied with their father; Camillo also studied in Rome. The two elder sons painted principally religious subjects in the tradition of Correggio. Camillo was a more successful colourist than his father, and Giulio Cesare followed the style of Correggio most perfectly of the three. Their paintings are found in the churches of Milan, Bologna, Genoa, and other Italian cities and hang in the galleries of most European capitals. They died in Milan. The youngest and least talented son painted still life and landscapes.

ERCOLE THE YOUNGER (1596–1676) was born and died in Milan. He studied with his uncle Giulio Cesare and was best known for his still-life pictures. On the death of Giulio Cesare, he became director of the academy.

PROCAINE HYDROCHLORIDE, generic name for a synthetically prepared local anesthetic also known by several trade names including Novocain, was introduced by Alfred Einhorn in 1905 as a substitute for cocaine. It is probably the safest local anesthetic agent for injection anesthesia (infiltration, nerve block, and spinal anesthesia). Its penetrating properties are poor, however, and when applied to mucous surfaces it is effective only in dangerously high concentrations. Unlike cocaine, procaine is not a habit forming drug. See also ANESTHESIA AND ANESTHETICS.

(F. O. K.)

PROCESSION, in general, an organized body of people advancing in formal or ceremonial manner. The term covers a wide variety of usages, both religious and civil. This article is concerned with the use of the term in the Christian Church, in which public processions seem to have come into vogue soon after the recognition of Christianity as the religion of the empire by Constantine in the 4th century. (For the Procession of the Holy Spirit, see HOLY SPIRIT.)

Roman Catholic Church.—Of the vast number of processions that developed during the Middle Ages, the more important and characteristic still have a place in the ritual of the Roman Catholic Church. These liturgical processions, carefully regulated by the church, are governed by rules laid down in the *Rituale Romanum* (Tit. ix) and are classified as ordinary or extraordinary. Ordinary processions are held on certain yearly festivals throughout the universal church and on other days according to the customs of the churches; e.g., in France on the commemoration of the vow of Louis XIII, Aug. 15. Extraordinary processions are those ordered on special occasions—e.g., to pray for rain or fine weather, in time of storm, famine, plague, war, or in any time of trouble, processions of thanksgiving, translation of relics, the dedication of a church or cemetery. There are also processions of honour—for instance, to meet the bishop on his first entry into his diocese.

Other processions characteristic of certain localities, though not regulated so strictly by the church and considered nonliturgical, play an important part in the religious life of the people; e.g., in the United States, May processions in honour of the Virgin Mary.

Antiquity and Provenance.—*Rogation Days.*—It is quite certain that one of the festivals in the pagan calendar of Rome involving a procession was adopted by the Christian Church. The Major Rogation (*litania maior*), an ordinary procession held on April 25, is the equivalent in the Christian Church of the Roman illustration of the crops in spring, the Robigalia, which consisted in a procession leaving Rome by the Flaminian Gate and proceeding by way of the Milvian Bridge to a sanctuary at the fifth milestone of the Via Claudia, where a dog and sheep were sacrificed to avert blight (*robigo*, wheat rust) from the crops. The Christian procession followed the same route as far as the Milvian Bridge, where it turned off and returned to St. Peter's where Mass was celebrated. This festival was already established as an annual event by the year 598, as is shown by a document of Gregory the Great (*Regist. ii*).

The Minor Rogations (*litaniae minores*), held annually on the three days before the Feast of the Ascension, were first introduced in Gaul by Bishop Mamertus of Vienne about the year 470 and were made binding for all Gaul by the first Council of Orléans (511). Later (c. 800) these were adopted in Rome by Leo III. It is possible that Mamertus first instituted the Minor Rogations to subrogate three days of pagan crop processions called the Ambarvalia (*q.v.*). (See also BOUNDS, BEATING THE; LITANY.)

Palm Sunday.—The modern Palm Sunday procession can be traced back to the Christian Church in Jerusalem in the 4th century, whence it spread to the West through the Frankish domains.

Purification.—The procession on the Feast of the Purification (or Candlemas), Feb. 2, might well be another instance of the church's subrogating a pagan lustral procession, for it is known that in pagan times another celebration of the Ambarvalia was held in the beginning of February, and Ildephonsus of Toledo seems to suggest that one was substituted for the other.

Stational.—Among the many types of processions which have fallen into disuse, one of the most important in terms of its splendour and the degree of its influence on subsequent liturgical practice was the papal "stational" procession. At least as early as the 8th century, the pope was accustomed to process with the whole papal court from the Lateran Basilica to a stational church somewhere in Rome. The faithful would arrive at the stational church in seven processions from the seven regions of Rome. The pope would then make a formal entrance into the church. The entrance procession was continued as a custom by the pope and the bishops of the Latin Church till the Middle Ages and still survives on one day a year, Holy Thursday. On special days, e.g., during Lent, the clergy and people would march from a central church with the pope to a stational church. The signs of reverence given to the pope as he entered the church are noteworthy. J. A. Jungmann claims that the thurible and seven torches carried by the acolytes in the pope's honour were marks of reverence to which the Roman emperor and higher state officials had been entitled.

Eucharistic.—The earliest records of the processions that formed part of the Christian ritual of the Eucharist, those of the entrance, the Gospel, and the Communion, date from the 6th century, though they were evidently established at a much earlier date. It is known that the offertory processions were continued, at least on great festivals, until the end of the Middle Ages, but by that time their true meaning had been lost and they were later discontinued. In the 20th century strong efforts have been made by liturgists to reintroduce the offertory and entrance processions.

The eucharistic processions still in use are of late origin: the procession on the Feast of Corpus Christi did not become general until the 14th century, and that in honour of the Blessed Sacrament on Holy Thursday was confirmed and adopted by John XXII (about 1333).

Orthodox Church.—The most noteworthy processions are the two connected with the celebration of the Eucharist. The first is the so-called "little entrance" before the reading of the Gospel in which the Gospel book is carried accompanied by lights and the singing of the *Trisagion* and other hymns. The second is the "great entrance" before the eucharistic prayer, when the offerings of bread and wine are carried in a more splendid procession, accompanied by ministers bearing fans representing angels' wings and the singing of the *Cherubikon*. The people's devotion has tended to centre around these processions because in the Orthodox churches a solid wall (*ikonostasis*) divides the sanctuary from the nave and hides the eucharistic celebration from the people.

Protestant Churches.—The Reformation abolished in all Protestant countries those processions associated with the doctrine of transubstantiation; "the Sacrament of the Lord's Supper," according to the 28th Article of Religion of the Church of England, "was not by Christ's ordinance reserved, carried about, lifted up, or worshipped." It also abolished those associated with the cult of the Blessed Virgin and the saints. The stern simplicity of Calvinism would not tolerate religious processions of any kind,

and from the Reformed Churches they vanished altogether. The more conservative temper of the Anglican and Lutheran communions, however, permitted the retention of such processions as did not conflict with the Reformed doctrines. The Lutheran Church in some localities has retained the ancient rogation processions during the week before Whitsunday and, in some cases, during the month of May. In the Anglican churches the funeral procession, the processional litanies, and the solemn entrance of the clergy and choir are still retained. The use of the processional cross, banners, and lights, long abandoned, has been revived.

PROCIDA (Latin *PROCHYTA*), an island off the coast of Campania, Italy, 2 mi. (3 km.) NE of Ischia and to the west of the Gulf of Naples. Pop. (1961) 9,050. It is about 2 mi. in length and, including the adjacent island of Vivara, is made up of four extinct craters; parts of the margins of all four have been destroyed by the sea. The highest point is only 250 ft. (76 m.) above sea level. The soil is very fertile. The only town, Procida, lies on the east side; its castle is now a prison. The island housed political internees for several years after 1945. (G. KH.)

PROCLAMATION, a historic form of executive action in England and the United States. In England, while the powers of parliament were evolving, the king in council still asserted and exercised a power to legislate, in the 14th century by ordinance and in the 16th and 17th centuries by proclamation. In 1539 the Statute of Proclamations (31 Henry VIII, c. 8) made a general authorization of legislation by proclamation which should "not be prejudicial to any person's inheritance, offices, liberties, goods, chattels or life" and of its enforcement by forfeitures and imprisonment. This statute was repealed, however, in 1547 by 1 Edward VI, c. 12, s. 5. In 1610 the opinion in the *Case of Proclamations* (12 Coke's Reports 74) declared that the king by his proclamation could not create an offense which was not one before; and this became unquestioned after adoption of the English Bill of Rights (1689). Royal proclamations are still employed in the second half of the 20th century, however, to give wide publicity to actions taken by the king in council, such as dissolving one parliament and summoning the next.

In the U.S. proclamations are issued by governors of states and mayors of cities; but of especial importance are those issued by the president, proclamations and executive orders being, aside from messages to congress, the chief kinds of formal presidential action. In U.S. presidential proclamations the body of the proclamation ("Now, therefore, I . . .") is preceded by a preamble ("Whereas . . .") and followed by the formula of attestation, the presidential signature, the seal of the U.S. and the countersignature of the secretary of state. The date is stated, by a tradition going back to President Washington, in terms of the independence of the U.S. as well as the Gregorian calendar.

Some proclamations of the president are merely informative or hortatory, while others are exercises of quasi-legislative authority delegated by statute or inferred from powers vested in the president by the constitution. Two of the most famous are Washington's proclamation of neutrality of April 22, 1793, and Pres. Abraham Lincoln's proclamation of emancipation of Jan. 1, 1863. Careful provision is made by law and executive order for the preparation, clearance and numbering of presidential proclamations and for their publication in the Federal Register. Proclamation of treaties is separately handled. (J. Hr.)

PROCLUS (*PROCLUS*) (A.D. 410-485), the most important representative of the later Neoplatonism inaugurated by Iamblichus (*q.v.*), was born at Constantinople of Lycian parents and brought up at Xanthus in Lycia. He studied philosophy under Olympiodorus the elder at Alexandria and then under Plutarch and Syrianus, the Platonic *diadochi* ("successors"), at Athens. He eventually became himself *diadochos* (*i.e.*, successor of Plato in the headship of the Platonic Academy at Athens) and held that position until his death in 485. An enthusiastic biography of him by

his successor Marinus is preserved.

Proclus is the most notable figure of the Athenian school of Neoplatonism, which was distinguished by its passionate paganism and by its taste for elaborate metaphysical speculation. He was probably not a very original thinker (we have too little detailed information about the works of his predecessors to be quite sure about the extent of his own contribution). But he was a great systematizer, expositor and commentator. The type of Neoplatonism which began with Iamblichus reaches its fullest development in the thought of Proclus, and it is through his works that we know it best. His chief importance in the history of philosophy is as one of the principal sources from which Neoplatonic ideas were diffused through the Byzantine and Islamic worlds and the medieval Latin west. He greatly influenced the Pseudo-Dionysius (Dionysius the Areopagite; *q.v.*), whose influence on the Christian thought of both east and west was immense.

Of the Arabic works which transmitted his ideas the most important was the so-called *Liber de causis*, which passed in medieval times as a work of Aristotle, though it is in fact based upon Proclus' *Elements of Theology* (as St. Thomas Aquinas, who knew both works in Latin translations, recognized). The *Liber de causis* and Proclus' own *Elements of Physics* were translated into Latin in the 12th century. Other Latin translations of important works of Proclus, including the *Elements of Theology*, were made in the next century by William of Moerbeke, the translator of Aristotle and friend of St. Thomas Aquinas. These translations, appearing at a time when very little of Plato and nothing of Plotinus was known in the Latin west, became for the later middle ages the principal source of their knowledge of Platonism.

The philosophical works of Proclus can be classified as follows: (1) his commentaries on Plato, of which those on the *Republic*, on the *Parmenides*, on the *Timaeus* and on *Alcibiades I* are extant with excerpts from that on the *Cratylus*; (2) his major exegetical work on Plato, the *Platonic Theology*; (3) two systematic manuals, the *Elements of Physics* and the *Elements of Theology*, the former being based on Aristotle's physical works, the latter, which is considerably more important, being a concise exposition of Neoplatonic metaphysics in 211 propositions; and (4) three occasional essays, the *De decem dubitationibus circa providentiam*, the *De providentia et fato* and the *De malorum subsistentia*, which survive only in the Latin translation of William of Moerbeke. Of his nonphilosophical writings there survive some astronomical and mathematical works, including the *Hypotyposis* on astronomical positions and a commentary on the first book of Euclid's *Elements*; some grammatical works (the identity of the author of the *Chrestomathia grammatica* with Proclus the philosopher is disputed); seven hymns and two epigrams, one of which (*Greek Anthology*, vii, 341) is an inscription for the common tomb of himself and his master Syrianus; and some fragments on religious-magical themes. See also **NEOPLATONISM**.

BIBLIOGRAPHY.—The best introduction to the thought of Proclus is to be found in *The Elements of Theology*, ed. with Eng. trans. by E. R. Dodds (1933). For the Platonic *Theology* recourse must still be had to the edition of Aemilius Portus (1618). The Teubner series includes the commentaries on the *Republic*, ed. by G. Kroll, 2 vol. (1899-1900); on the *Timaeus*, ed. by E. Diehl, 3 vol. (1903-06), on the *Cratylus*, ed. by G. Pasquali (1908), and on Euclid, ed. by G. Friedlein (1912); the *Elements of Physics*, ed. with Ger. trans. by A. Ritzenfeld (1912); and the *Hypotyposis*, ed. with Ger. trans. by C. Manitius (1909); and the *Hymns*, ed. by A. Ludwig with the poems of the empress Eudocia (1897). The part of the commentary on the *Parmenides* that survives in Greek, the commentary on *Alcibiades I* and the three essays *De decem dubitationibus*, *De providentia et fato* and *De malorum subsistentia* are printed in V. Cousin, *Procli opera inedita* (1864); for the important final section of the commentary on the *Parmenides*, extant only in the medieval Latin trans., see R. Klibansky and C. Labowsky (eds.), *Plato latinus*, vol. iii (1953). The commentary on the *Parmenides* is also ed. by G. Stallbaum (1840) and that on *Alcibiades I* by L. Westerink (1954).

Thomas Taylor's English translation of the works of Proclus comprises *Philosophical and Mathematical Commentaries of Proclus*, 2 vol. (1788-89; reissue 1792), including the commentary on Euclid and the *Life of Proclus* by Marinus together with the *Elements of Theology*; *The Six Books of Proclus . . . on the Theology of Plato*, 2 vol. (1816); with the three philosophical essays; the commentary on the *Timaeus* (1820); *The Fragments* (1825); and a separate edition of the *Two*

Treatises . . . of the Ten Doubts Concerning Providence and . . . of the Nature of Evil (1833).

The text of the *Life* by Marinus, ed. by J. Boissonade, is appended to C. G. Cobet's edition of Diogenes Laërtius (1850). For a detailed account of Proclus' thought, with a survey of the literature and an English version of Marinus, see L. J. Rosán, *The Philosophy of Proclus* (1949). See also T. Whittaker, *The Neo-Platonists*, 2nd ed. (1918). (A. H. Ae.)

PROCONSUL, the generic name of a type of fossil ape, a few fragmentary remains of the jaws of which were found in Miocene Epoch deposits in Kenya in 1931. The British-Kenya expedition of 1947 discovered more remains of this creature, including many jaws and teeth, a few limb bones, and the greater part of a skull—the first known example of a fossil ape's skull of such antiquity. The expedition's collections also showed that east Africa during the Miocene was inhabited by a remarkable variety of anthropoid apes, including species of *Proconsul* ranging in size from that of a small chimpanzee to a gorilla. A study of the limb bones led to the conclusion that these fossil apes were far more generalized in limb structure and proportions than modern apes. While evidently beginning to assume the arboreal habits of the modern apes, they still possessed features found only in the more primitive monkeys of today. *Proconsul* thus provides concrete evidence of a stage in the evolutionary transition from tailed monkeys to true anthropoid apes—a transition long postulated on the indirect evidence of comparative anatomy. *Proconsul*'s non-specialized morphology provides some reason for supposing that it may have been closely allied with the extinct group from which both man and the modern anthropoid apes were derived.

See **PRIMATES: Origin and Relationships**; **AFRICA: Archaeology: Fossil Hominid Remains**.

See W. E. Le Gros Clark and L. S. B. Leakey, *The Miocene Hominoids of East Africa*, "Fossil Mammals of Africa Series" no. 1 (1951); J. R. Napier and P. R. Davis, *The Fore-limb Skeleton and Associated Remains of Proconsul africanus*, "Fossil Mammals of Africa Series" no. 16, British Museum of Natural History (1959). (W. E. L. G. C.)

PROCOPIUS (fl. first half of 6th century A.D.), Byzantine historian whose works are an indispensable source for his period and contain much geographical information, was born at Caesarea in Palestine, probably between the years 490 and 507. He had a legal training and from 527 to 531 was adviser (*consiliarius*) to the military commander Belisarius (*q.v.*) on his first Persian campaign. In 533 and 534 he took part in the expedition against the Vandals and was in Africa until 536 when he joined Belisarius in Sicily. He was in Italy on the Gothic campaign until 540, after which he apparently returned to Constantinople, since he describes the great plague of 542 in the capital. Nothing is known with certainty of his subsequent life. He may have been prefect of Constantinople in 562.

Procopius' writings fall into three divisions: the *Polemon* (*De bellis*; *Wars*, Persian, Vandal, and Gothic), in eight books; *Peri Kismaton* (*De aedificiis*; *Buildings*), in six books; and the *Anecdota* (*Historia arcana*; *Secret History*), which was only published after the author's death.

The *Wars* consist of: (1) the Persian Wars (two books), on the long struggle of the emperors Justin I and Justinian I against the Persian kings Kavadh and Khosrau I down to 549; (2) the Vandal War (two books), describing the conquest of the Vandal kingdom in Africa and subsequent events from 532 to 548; (3) the Gothic War (three books), describing the war against the Ostrogoths in Sicily and Italy from 536 to 551. The eighth book contains a further summary of events down to 553. These books also refer to certain important internal events, such as the Nika insurrection at Constantinople in 532 and the plague in 542.

The *Buildings* contains an account of the chief public works undertaken during the reign of Justinian down to 560. If not written at the command of Justinian (as some have supposed), it is evidently grounded on official information, and is full of panegyric of the Emperor and the late Empress, but is nevertheless a valuable source of information.

The *Secret History* purports to be a supplement to the *Wars*, containing explanations and additions which the author could not insert into the latter work for fear of Justinian and Theodora. It is a violent invective against these sovereigns, with attacks on

Belisarius and his wife Antonina, and on other noted officials. Owing to the ferocity of the attacks upon Justinian, the authenticity of the *Secret History* was questioned, but Procopius' authorship is now generally recognized. In point of style, the *Secret History* is inferior to the *Wars*, and has the air of being unfinished, or at least unrevised.

PROCRUSTES, also called **POLYPEMON** or **DAMASTES**, in Greek legend, a robber dwelling in the neighbourhood of Eleusis, who was slain by Theseus (*q.v.*). He had an iron bed (or according to some accounts, two beds) on which he compelled his victims to lie, stretching or cutting off their legs to make them fit the bed's length. The "bed of Procrustes" has become proverbial for inflexibility.

PROCTOR, a variant of the word procurator, nearly equivalent in meaning to agent; it is now obsolete in English except for certain technical meanings. In law, it was formerly applied to a practitioner in ecclesiastical and admiralty courts, licensed by the archbishop of Canterbury to perform such duties as were performed by solicitors in ordinary courts. With the passing of the Judicature Act, 1873, proctor in this sense became obsolete, the term solicitor being extended to include proctors. (See **LEGAL PROFESSION: England and Wales**.) However, the word is still sometimes used in the United States to denote any practitioner in probate and admiralty courts; another trace of it remains in the office of queen's proctor, who represents the crown in British divorce courts and has a duty to expose collusion between the parties.

In the Church of England a proctor is a representative of the clergy in convocation; at certain universities—notably Oxford and Cambridge—a proctor is a university official charged primarily with the enforcement of discipline among undergraduates.

PROCUREMENT, MILITARY. This term denotes the acquisition by a military establishment of goods and services, other than military personnel, whether by purchase, rent, lease, manufacture or requisition. It includes determination of requirements, drafting of specifications, selection of sources of supply, determination of contractual terms, inspection of matériel procured, and the payment and audit of accounts.

The importance of military procurement arises from its effects on the nation's economy. Poor procurement practices may promote social tensions and economic instability, and low civilian standards of living. As the art of warfare has become more complicated in the 20th century, procurement has taken on increased importance. In the United States at the peak of World War II, military requirements absorbed about 44% of the gross national product; in Great Britain and Germany about 50%; in Japan 41%. Even in the peacetime years of the early 1960s military requirements absorbed about 10% of the gross national product in the United States.

Requirements.—Making accurate estimates of requirements in the light of strategic plans is essential to effective procurement. This process involves two steps: (1) determination of the requirements for various end products; (2) the conversion of requirements for end products into requirements for labour, material and productive facilities, and their comparison with available resources in order to determine whether or not strategic plans are feasible. In determining its requirements a country inevitably takes calculated risks and chooses between alternative strategic plans in the light of their costs. Since the impact of procurement on the economy depends upon its timing as well as its magnitude, it is important that requirements be properly phased. Unnecessary strain may be placed on the economy if, for example, contracts for the delivery of ammunition in six months are placed while the weapons that are to use the ammunition will not be ready for two years.

Once the requirements are set up, the objectives of procurement policy are several: (1) fulfillment of requirements in the volume and quantities and at the time and place needed; (2) efficient utilization of resources so that requirements may be fulfilled with minimum impact upon civilian standards of living; (3) budgetary economy; (4) economic stabilization; and (5) sociopolitical objectives, such as elimination of excessive profits, fostering of small business and elimination of discrimination in employment practices.

Most governments have reserved the power to requisition goods and services in times of emergency, but in recent times this power has been used cautiously. Countries vary in the extent to which the government itself undertakes the manufacture of military equipment. In the United States, Great Britain and Germany the military establishments have relied heavily upon purchases from private enterprise.

Purchasing Techniques.—Two principal purchasing techniques are used in military procurement: the system of public advertising for sealed bids; and the negotiated contract. Under the sealed-bid system the contract is normally awarded, after public opening of the bids, to the lowest responsible bidder who meets the advertised specifications. Consequently, once specifications are determined, the purchase function becomes routine and opportunities for favoritism in selecting suppliers are minimized. Moreover, where there is genuine competition the system protects the financial interest of the government.

Often the sealed-bid system is not a useful device and is replaced by the negotiated contract. Since the procurement officer will frequently negotiate with several sources of supply, negotiation does not preclude competition. Frequently it is desirable to award an unpriced "letter of intent" before specifications can be put in final form and bids sought so that the supplier may have a head start in tooling up, placing orders for materials and recruiting a labour force. In other cases national security makes it inadvisable to publicize specifications. In some industries strategic planning requires the maintenance in readiness of several geographically dispersed sources of supply. Often it is desirable to place contracts in the light of the availability of manpower or other scarce resources rather than on the basis of price alone. In the case of research and development contracts, where confidence in a particular supplier is paramount, selection of a supplier on the basis of a low bid is not practicable. Likewise, where suppliers are few or where costs are uncertain because of rapid change in design or in the rate of output, the sealed-bid system may not be the most efficient way to develop a competitive price. Finally, in situations where military needs can be fulfilled by several products of similar but slightly different specifications, the interest of the government may lie in negotiating on specifications as well as price.

When an economy operates under a general system of price control, the question arises whether such controls should apply to military contracts. In Britain and the United States during World War II, responsibility for the prices of specialized military equipment was generally placed on the procurement agencies while prices on contracts for standard commercial items were subject to the general controls. This practice facilitates the diversion of economic resources to military needs by leaving the military establishment free to attract suppliers by price incentives and relieves price control authorities from possible charges of interfering with the military program.

The system of negotiation permits the tailoring of contract terms to the circumstances of the particular procurement. There are several basic types of contracts in common use. The type selected in a particular case will depend in part on the relative emphasis on providing incentives to efficient production in contrast to controlling profits. The simplest type of contract is the fixed price contract. It is the easiest to administer and provides the supplier maximum incentives to control costs. The central problem in the use of this type of contract is arriving at a reasonable price; where there is previous experience in producing similar items under similar conditions or where there are alternative suppliers, it may not be difficult. However, in the absence of good cost estimates, unexpectedly large profits may develop, not because

of the effectiveness of the supplier in controlling costs but because of ignorance in estimating costs when the contract is negotiated.

Cost plus contracts are widely used where there are difficulties in estimating costs. Under such contracts the supplier receives a fee for his services as well as reimbursement for his allowable costs. The earlier practice of calculating the fee as a percentage of actual costs left the supplier with a positive incentive to increase his costs. The cost plus-fixed fee contract (CPFF), in which the absolute amount of the fee is predetermined, eliminates the incentives to cost inflation and minimizes the possibilities of excessive profits but provides no financial incentives to cost control. The administrative disadvantages of cost contracts are great, since they require careful audit of the supplier's accounts to verify his costs and frequent inspection of his operations to ensure efficient use of resources.

There are many variations of these two basic types of contracts. Incentive features may be added to cost contracts by providing that the fee shall not be fixed but shall depend upon the extent to which the contractor exceeds or falls short of some target cost. Nonprofit organizations often operate under cost contracts without any fee. Fixed price contracts have been modified in many cases to provide for redetermination of price at some time during the life of the contract on the basis of actual cost experience. A fixed price contract may include an escalator clause providing for change in price in the event of some increase in labour or material costs. Such a clause, by relieving the contractor of risks over which he may have no control, makes it possible to eliminate from the contract price an allowance for contingencies.

In the United States, in particular, there has been considerable concern over the tendency to place military contracts with the larger suppliers, popularly known as "big business." This concern arises in part because of the fear that military procurement will accentuate monopolistic tendencies and in part because of the need during periods of mobilization to use all productive facilities. Consequently, various devices have been adopted for encouraging the dispersing of contracts among small businesses.

Profits.—Control of profits often plays a large part in procurement policy. Because of difficulties in negotiating close prices on many contracts, profits often turn out to be larger than anticipated. Various noncontractual devices have been tried for recouping excessive profits. Many countries at one time or another have enacted excess profits taxes, which usually take normal peacetime rates of profit as a basis for estimating allowable profits during periods of mobilization. Since 1942 the United States has experimented with a system of contract renegotiation designed to recapture excessive profits at the end of the year after review of the supplier's over-all profit-and-loss position on his government business. In determining whether or not a contractor has excessive profits the renegotiation authorities are required by statute to consider various factors, including the contractor's promptness in delivery; the quality of his product; his risk; and his efficiency. The renegotiation procedure establishes a pattern of allowable profits which serves as a guide to suppliers and procurement officers in their negotiations. It also serves to eliminate excessive profits arising from errors in judgment, deficiencies in contract negotiation or from the efforts of a willful minority to take advantage of the government. While the elimination of excessive profits serves important social purposes, some students believe that the renegotiation process as practised is to some extent in conflict with the objectives of controlling costs and prices. Moderate profits do not ensure low prices and low costs.

Another important problem facing procurement officials is the control of prices on subcontracts. This may be achieved in part by direct price controls on many standard items, by renegotiation and by excess profits taxes. Other attempts to control subcontract prices directly have generally met with limited success.

Centralization.—There has been much public discussion in the United States of the relative merits of centralization of procurement in a single agency as against decentralization into various divisions of the armed services. During World War II, each of the armed services was responsible for most of its own procurement, and within each of the services procurement was further decentral-

ized to the technical bureaus or services. Although the army, navy and air force have since been absorbed into the department of defense and the formulation of procurement policy and the purchase of some items common to the various services have been centralized, the responsibility for the procurement of most specialized military equipment is still decentralized to the component services.

(J. P. M.)

PROCYON, the brightest star in the constellation Canis Minor (see CANIS MAJOR), hence its Bayer equivalent, α Canis Minoris. It and Sirius (*q.v.*) in Canis Major were called the two dog stars, though Dog Star refers to Sirius, which is the brighter of the two. Procyon is a double star consisting of one bright and one very faint component. It is located at a distance of about 11 light-years from the sun and is therefore one of the nearest stars.

PRODICUS OF CEOS (*c.* 465–after 399 B.C.), Greek sophist, came to Athens from Ceos and became known as a lecturer, writer, and teacher. He appears as a character in Plato's *Protagoras*. His *Horae* contained the famous story of the "Choice of Hercules" summarized in Xenophon, *Memorabilia*, ii, 1, 21 seq. He held that the gods were natural objects and forces, together with deified benefactors of mankind. He was also interested in morals and physical science. A lecture or course of lectures *On the Right Use of Words* distinguished between apparent synonyms and influenced Socrates, Plato, and others. For fragments and testimonia see H. Diels and W. Kranz, *Fragmente der Vorsokratiker*, vol. ii, 7th ed. (1954).

(G. B. Kn.)

PRODIGY, although it may refer to any extraordinary, astonishing person, event or deed, has been particularly applied to children who show early signs of genius or exceptional ability along certain lines. Among these are the arithmetical prodigies; the chess prodigies; and the lightning calculators, who have a remarkable memory for figures and vivid visual or auditory imagery, but often do not excel in other ways. Best known are the musical prodigies—Mozart, Schubert and Mendelssohn, all of whom began to compose before the age of 12; Johann Hummel, Chopin and Yehudi Menuhin, who gave public concerts by 11 years of age; and Ruth Slenczynska, who astounded audiences at 6; Brahms, Dvořák and Richard Strauss all drew musical attention early.

Far less common is precocious ability in acting, writing, drawing and painting, such as that of the famous 19th-century child actor William Betty, popularly known as "the young Roscius"; Minou Drouet, who in 1856 at the age of 8 won fame for poems and letters of doubtful authenticity; and Albrecht Dürer, who painted a self-portrait at 13. Pascal at 11 secretly constructed a geometry of his own; Norbert Wiener and Fred Safer, Jr., read science and literature at 5 years and entered college by the age of 12.

How do children become prodigies? They are both born and made—born with retentive memories and a quality of mind that enables them to relate and organize experiences; made in the sense that they receive opportunities and rewards and special practice, instruction or training. The three prodigies last mentioned had radically different home environments. When Pascal was 11, his father deprived him of mathematical books. In marked contrast, Norbert Wiener was subjected to his father's insistent, severe and often painful demands for precise and ready knowledge. Fred Safer's parents, on the other hand, reported that they never pushed the boy but encouraged him to cultivate varied interests.

Do prodigies fulfill the promise of youth? Few mental prodigies reported in history have met early expectations. (The German prodigy Christian Heineken [1721–25], said to have learned to speak Latin and French by the age of three, and to be capable of publicly demonstrating knowledge in history, geography and biblical study, died at the age of four.) However, musical prodigies seldom fade into oblivion. Original, creative geniuses who achieve

the highest eminence could probably have been identified as extraordinary in early childhood. See also GIFTED CHILDREN; GENIUS.

(R. U. S.)

PRODROMUS, THEODORE (d. *c.* 1166), sometimes called Ptochoprodromus ("poor Prodromus"), a Byzantine writer, well known for his prose and poetry, some of which is in the vernacular. He wrote many occasional pieces for a widespread circle of patrons at the imperial court. Some of the work attributed to him is unpublished and some of it may be wrongly attributed to him. Even so there does emerge from these writings the figure of an author in reduced circumstances, with a marked propensity for begging, who was in close touch with the court circles during the reigns of John II and Manuel I (1118–80). He was given a prebend by Manuel I, and he ended his life as a monk. Behind panegyric and conventional treatment his writings, often written on the occasion of some public event, provide the historian with vital information on many aspects of contemporary history, both at home and abroad, including details on genealogy, on individual personalities, on everyday social and economic life. There is a strongly satirical vein in his works, which range from epigrams and dialogues to letters and occasional pieces in both prose and verse. He had a biting sense of humour and his comments are shrewd and pithy.

BIBLIOGRAPHY.—Some works in J. P. Migne, *Patrologia Graeca*, vol. 133 (1864), and D. C. Hesselung and H. Pernot, *Poèmes prodromiques en grec vulgaire* (1910); others widely scattered in various publications. See also K. Krumbacher, *Geschichte der byzantinischen Literatur*, 2nd ed., pp. 749–760 and 804–806 (1897); G. Moravcsik, *Byzantinoturcica*, vol. 1, 2nd ed., pp. 522–526 (1958); G. Ostrogorsky, *History of the Byzantine State*, p. 314 (1956); A. A. Vasiliev, *History of the Byzantine Empire*, pp. 500–502 (1952); P. Lamma, *Comneni e Staufer*, 2 vol. (1955–57).

(J. M. Hy.)

PRODUCTION, CENSUS OF. A census of production is an enumeration of units of production in much the same sense that a population census (see CENSUS) is an enumeration of people. However, since the object of the enumeration in a production census is not precisely defined, such censuses are different from population censuses. The latter have in all times and places exhibited similar characteristics because they have been concerned with an easily identified unit of enumeration. Ideas as to which units of production are suitable for enumeration have differed greatly at various times and places; some countries, for example, have used the individual establishment or workshop while others have used the entire enterprise, regardless of the number of establishments it contained. The concept of production itself has also changed from time to time in accordance with prevailing economic ideas. Thus, the French physiocratic school (*q.v.*) in the 18th century held that only agriculture was really production, while in the Soviet Union and other Communist countries in the 20th century, many services are not considered to be part of the production total. In the non-Communist world, however, the terms "economic activity" and "production" are largely synonymous.

Because the term "census" connotes comprehensive coverage of an entire area or country, modern usage would require that the term "census of production" should cover the total production of the country or area, without qualification. Nevertheless, the term "census of production" has been used traditionally in certain countries, notably the United Kingdom, to denote periodic censuses of the output and characteristics of industrial establishments. Other countries use the term "census of manufactures," "census of industry," or "census of industrial production." The tendency in modern practice is to approach the problem of enumerating productive units by means of censuses of agriculture, censuses of manufactures and mining, and censuses of distribution or business which, together, cover the bulk of production as understood by economists in non-Communist countries.

Historical Development in U.S.—The progression of ideas which has led to, and which explains, much of present theory and practice in production censuses is nowhere seen more clearly than in the historical development of the subject in the United States, which was the first country to take a comprehensive approach. In 1810, the U.S. Congress amended the statute governing the

population census for that year to instruct U.S. marshals, who were then enumerators for the population census, to "compile an account of the several manufacturing establishments and manufactures within their several districts, territories and divisions." To implement this legislation, a circular was drawn up by Tench Coxe, an assistant to the secretary of the treasury and a remarkable pioneer in the field of official statistics. The circular, which is notable for its foresight as to the kind of data required, set out a sample of the information to be collected:

"George B. Williams, of the township of Northhampton, county of Berkshire, and state of Massachusetts, makes and sells broad cloths at two dollars and one-half, to three dollars per yard; blankets at three to three dollars and one-half each; narrow cloths at one dollar and one-third, to one dollar and one-half per yard; total of goods in a year, 4,231 yards of broad cloth, 7,368 yards narrow cloth, and 413 blankets. Total value, 25,511 dollars and 45 cents.

"The said George Williams employs and moves by water one carding machine and 150 spindles; and by hand four hundred and ten spindles in the woolen manufacture."

Coxe tabulated the information received to show the number of firms in each state and county and the quantities of each commodity produced. The incompleteness and inaccuracies of the census of 1810 were analyzed by Adam Seybert in his *Statistical Annals* (1818); he concluded that the census would be improved by the use of a detailed questionnaire and by giving proper instructions to the enumerators. He recommended a questionnaire which constitutes a model and which, in broad outline, remained unchanged up to modern times. The data to be collected for each establishment consisted of: (1) the county and state in which located, (2) the nature of the manufacturing process, (3) the quantity of each raw material used and the total cost thereof, (4) the number of persons employed and the amount of their wages, (5) the capital invested, (6) contingent expenses, and (7) value of production. These questions, plus a question on machinery employed, were embodied in the questionnaire used in the census of 1820, taken as part of the population census of that year.

The process by which the information given by the individual firms in the census of manufactures is put together to yield information on the entire economy is best seen by consideration of an actual census form. The census form shows the first page of the information given by E. I. du Pont de Nemours in the census of 1820. Only its antiquity and its historic interest permit the reproduction of this material, for information relating to individual firms is kept strictly secret in the production censuses of all countries and is not divulged by the statistical authority even to other departments of government. The forms are first classified according to industries; in this example the data belong to the chemical industry. An important aggregate is obtained by determining the total value of the products of each establishment; in the example this amounts to 606,000 lbs. of gunpowder valued at 17 to 22 cents per lb., or approximately \$118,000. This aggregate for all establishments in the country will include not only the value of the production of each establishment, but will contain duplications of products produced in one factory and consumed in another. Consequently, the net contribution of each establishment to production is obtained by deducting the value of materials used from the value of the products. The resulting aggregate is called the value added by, or the net output of, the field covered by the census. In the example shown, since the value of the products was \$118,000, and the value of materials \$55,670, the net output of that establishment was \$62,330. Modern census questions differ from those answered here only in the degree of detail requested and by the addition of questions on capital expenditure, together with certain items necessary to ensure absence of duplication in the calculation of the net output. These questions are relatively easy to answer in countries in the early stages of industrialization, but they become increasingly difficult as the economies develop. Some idea of the complexity of the modern census can be obtained by considering the entries that are required today to show the same data for the establishments which, in the course of time, have grown out of the simple "Gun Powder manufactory on the Brandywine." The current capital value of the Dupont enterprise is measured in billions of dollars and the net

Gun Powder manufactory on the Brandywine.	
Raw materials Employed	1. Salt Petre, Brimstone and charcoal 2. Refined Salt Petre, 454,000 lb. Roll brimstone, 70,000 lb. Charcoal, 82,000 lb. 3. Cost of raw material, \$55,670
Number of Persons Employed	4. Ninety Five men. 5. None 6. None 7. and 8. Six mills and a number of other buildings for manufaturing purposes.
Expenditures	9. Capital Invested \$240,000 10. Wages, \$36,300 11. The contingent expenses comprehend many different kinds of expenditures, as cooerage, freight, carriage, commission to agents, etc., the amount of which cannot be known—the cost of occasional explosions, which are also a kind of contingent expense peculiar to the manufacture of Gunpowder cannot be easily estimated.
Production	12. Principally fine Gunpowder for shooting, and occasionally common and musket Gunpowder. 13. Market value from 17 to 22 cts per pound. 14. The establishment is composed of two complete Gunpowder manufactories, situated on the Brandywine, the first, the Eleutherian Mills, was erected in 1803 and the other, Hagley, in 1813. The whole amounts

output alone exceeds \$1,000,000,000; the number of separate establishments that produce the output is greater than the number of men employed at the time of the first census and the range of products covers several different industries. For this reason, large enterprises are requested to provide data on each separate establishment, which is then classified into the individual industry which forms the greater part of its activities.

Economic Significance of Data.—The sum of the net outputs of all establishments in an industry, or in all the manufacturing industries of a country, is a most important figure, since it measures, with certain deductions, the contribution of the industries to the national product. Moreover, it provides the basis for many kinds of economic analysis, because it reveals the economic cost of each commodity produced, together with details of the nature of these costs, in terms of labour, material, fuel and other inputs. The relation between net output and capital invested is used to measure the productivity of capital; the relation between net output and employment is used to measure the productivity of labour. The sum of wages and salaries gives the share of labour in the output of industries; the remainder of the output covers the returns to the other factors of production and the smaller business expenses. Changes in these relationships are of considerable economic significance. The modern census tends to collect more information on plant and equipment because of the importance of plant and equipment as indicators of economic growth. Moreover, to obtain the true net output generated by industry, it is necessary to deduct the value of capital consumed in the process of production. This is done by means of estimates for depreciation and obsolescence of the plant and equipment. Distinction is also made between the activities of the establishment that are directed toward producing goods for current consumption and those that result in the formation of new capital equipment.

Current Census Developments.—It is generally the practice that the unit enumerated is the establishment rather than the enterprise. Some problems arise in defining these terms, but generally an establishment is defined as an individual plant at a single location as distinguished from an enterprise composed of more than one plant, each of which may manufacture different products. In the case of the establishment, it is possible to associate statistics on the goods produced with the geographical location of the plant and with labour and other resources consumed in production. Unless it is a single-establishment enterprise, however, it becomes extremely difficult to associate statistics of plant operations with the financial data, which are normally available only for the enterprise as a whole. For this reason, censuses in

highly industrial countries have added a question designed to enable the census authorities to identify the establishments that comprise a single enterprise. By collecting these establishments together, aggregates can be obtained to show the overall production, field of activity, employment, and net output of enterprises. By means of these data, calculations can be made of the degree of concentration of industry by calculating the percentage of employment and the percentage of net output achieved by firms of each size, ranging from small firms to industrial giants. Moreover, the data on enterprises can be associated with the accounting data of the enterprises concerned so that the productive achievement can be associated with the assets, state of indebtedness, and profits and losses of the enterprises.

The census operation involves the enumeration of units at a point in time, but production itself is not measurable at a point in time. Productive instruments, such as installed machinery and equipment, factories, and workshops can be enumerated on a given census date, but the quantity and value of production represent a flow over a period of time. As a result, some countries have concentrated on measuring the flow of production and others on measuring the productive establishments. In the United States and the British Commonwealth the main emphasis has been on the collection of data on the output of goods (*i.e.*, flow data) under the title of Census of Production in the United Kingdom and Census of Manufactures in the United States. In continental Europe, on the other hand, the main emphasis has been laid on the collection of data on the structure and distribution of productive resources under a general heading such as Census of Establishments. These differences in purpose and emphasis are discernible in the information collected and the fields covered. The production approach concentrates on (1) quantity and value of goods produced and materials used up in the process, and (2) the factors of production involved. The Census of Establishments concentrates on (1) the number, nature, location, and size of production units, such as factories, and (2) equipment and employment. Both types of census were originally taken only at infrequent intervals and were usually adjuncts of the population census or closely related to it.

For highly industrialized countries, the census of production is a complex and lengthy operation involving the questioning of each individual establishment, the processing of the returns, and the publication of the final results. While the use of automatic data processing equipment has greatly speeded up the handling of the collected material, there is nevertheless a long interval between the period to which the data relate and the date of their publication. This delay has tended to limit the usefulness of the census for purposes of current economic analysis. In consequence, some countries have adopted methods to speed up the collection, compilation, and publication of results. They mail questionnaires directly to the large producers, omit very small producers (*e.g.*, those employing less than ten workers), and estimate the production of small producers by means of probability samples, in which only a small percentage of producers are questioned by means of a brief questionnaire. An example of these devices was provided by the United Kingdom Census of Production in 1959, which was described as "the first of a new series of simple annual enquiries following the detailed census taken for 1958." (*See "Census of Production Results for 1959," Board of Trade Journal, Dec. 2, 1960.*) This inquiry was confined to three items—value of goods sold and work done, stocks and work in progress, and capital expenditure. More important, however, was the fact that instead of using the establishment as the basic statistical unit, the figures collected related to all the business of each firm, company, or group of companies operating in each industry. If the firm was engaged in a number of different activities, separate returns were required for each main activity. The inquiry was confined to firms employing 25 persons or more. Estimates were made for firms employing less than 25; these small firms constituted only 10% of total sales in the more detailed 1958 census.

In a similar development, the Netherlands government made a series of annual inquiries to collect the main data which, in other countries, are collected in infrequent censuses. These devel-

opments, designed to yield more up-to-date figures, have occurred in the countries using both the production census approach and the establishment census approach with the consequence that the census proper, as distinct from the more frequent surveys of production that are made annually or at other intervals, has tended to become an operation which provides the basic data necessary for the regular and current series of statistics that provide measurements of a country's production. The census has, therefore, changed from an operation designed to measure production and the production structure at infrequent intervals to one providing the framework and the basic elements for a system of current production statistics.

Current Production Statistics.—Current measures of the level of economic activity, both in the aggregate and for the principal components, are required by all countries and are particularly important in highly developed economies. In these economies, progress in knowledge of the monetary, fiscal, and other measures that can be taken to offset industrial fluctuations in the short term, and to stimulate economic growth in the long run, has brought about a realization of the need for current measures of the main elements of industrial activity. This need has been met in many countries by the development of indexes of industrial production, compiled monthly, quarterly, and annually, on the basis provided by the census data. (*See ECONOMIC PRODUCTIVITY.*) The problem here is to select such elements of the census aggregates as can be conveniently and inexpensively measured in each current period, and which can be compiled quickly into aggregates that will reflect conditions in the entire industry or industries concerned. Thus, from the census data a sample can be drawn of establishments or enterprises or products that will form the basis of monthly or quarterly reports on production and other characteristics. Frequently a separate sample is taken from the large producers, as revealed by the census, since they can report in considerable detail on the basis of up-to-date accounting records. The smaller producers may be required to provide data at less frequent intervals or in less detail. The units thus selected report regularly the quantity and value of goods produced, or even merely the principal items of production. For each branch of industry, or for each product, the quantity of the output in the current period is compared with that of the base period, usually the census year, to obtain the "quantity relative", *i.e.*, the percentage which current output bears to the base output.

The process is simple when homogeneous items are involved, *e.g.*, bicycles, or tons of cement; but when heterogeneous items are involved, such as textiles and clothing, it is frequently necessary to take the value of the products in the current period and deflate it by means of a price index to obtain the value of current production at the prices of the base year. This value, compared with the value of base year production, also yields a quantity relative. In cases where it is not possible to obtain a quantity relative for the outputs, resort is had to a quantity relative of the inputs where it is known that there is a constant relationship between input and output, *e.g.*, steel ingots consumed in the fabrication of structural steel products provide a reliable measure of the output. In other cases resort may be had to the input of operative man-hours as an indication of the output. By such devices a series of quantity relatives is obtained, which gives the relation between production of each item in the current period and production in the base period. These quantity relatives are embodied in a summation in which each of them is weighted by the value added, or net output, of each item as revealed by the census data. The results are then published as the percentage which production in the current period bears to production in the base period.

Production Index Formulas.—The formula used for a production index depends largely on the type of basic data available. The formula usually employed is the aggregate form of the Laspeyres type, viz:

$$Q_{01} = \frac{\sum p_0 q_1}{\sum p_0 q_0} \quad (1)$$

where the subscripts 0 and 1 relate to the base period and the current period respectively, p (shorthand for p_i) represents the prices, with the reservation stated below, and q (shorthand for

q_i) the quantities, and Σ (shorthand for $\sum_{i=1}^n$) indicates the sum-

mation over all the items included in the calculation of the index. Substantially the same result is obtained by weighting the quantity relatives for each item by their value in the base year, thus,

$$Q_{01} = \frac{\Sigma p_0 q_0 \left(\frac{q_1}{q_0} \right)}{\Sigma p_0 q_0} \quad (2)$$

In cases where quantity relatives are not available, the value of the items produced in the current period may be converted to base year prices by the following formula:

$$Q_{01} = \frac{\Sigma p_1 q_1 \left(\frac{p_0}{p_1} \right)}{\Sigma p_0 q_0} \quad (3)$$

Each of the formulas above can be changed to the Paasche form by the substitution of prices of the current period in place of the prices of the base period:

$$Q_{01} = \frac{\Sigma p_1 q_1}{\Sigma p_1 q_0} \quad (4)$$

$$Q_{01} = \frac{\Sigma p_1 q_1}{\Sigma p_1 q_1 \left(\frac{q_0}{q_1} \right)} \quad (5)$$

$$Q_{01} = \frac{\Sigma p_1 q_1}{\Sigma p_0 q_0 \left(\frac{p_1}{p_0} \right)} \quad (6)$$

Furthermore, each of the formulas (1), (2), and (3), which use base prices as weights, can be averaged geometrically with formulas (4), (5), and (6), respectively, which use current weights, in order to yield Fisher's so-called "Ideal" formula.

In the above examples, the letter p has been used to represent prices. It is important to observe that where these prices are the actual commercial or producers' prices of the individual commodities involved, the index that results is a "gross weighted" index. Where the p 's represent not prices in the normal sense, but the added value, or net output, per unit, attributable to the item, then the index is a "net weighted" index. The difference between these two types of indexes is important. In general, the production indexes published by the U.S.S.R. and Eastern European countries are gross weighted indexes, while those which are common in Western Europe, the United States, and the Commonwealth are based on the principle of net weights. It should be noted, however, that it is extremely difficult to obtain a complete set of net weights for all items of the production index. This is because the various products issuing from productive establishments can seldom be analyzed in such detail as to establish the value added output content of each item, because many of the costs for raw materials and fuels cannot be apportioned precisely to the individual products but are available only as an aggregate for all the products of the establishment. Consequently, it is common practice to use the relative values of gross output, with or without adjustment, to obtain the weights within each industry, or each similar subdivision of the total index (e.g., individual industry or sub-industry). For each industry as a whole, however, and also for certain subdivisions of industries, the census provides the value of the total output and the value of the corresponding input, the difference between the two being the value added as given by the census. Consequently, for each industry (or subdivision) weights can be obtained which are based completely on value added.

The difference between the U.S.S.R. and the Western countries in the construction of index numbers of industrial production is of a conceptual rather than a practical kind. The Western countries seek to obtain a measure of the change in the "work achieved" by the industrial sector of the economy in successive periods of time (monthly, quarterly, annually) and this involves the elimination, from the calculation, of those products or outputs which are consumed (i.e., constitute inputs) within the sector being measured. In the U.S.S.R., while this same concept is used in the national accounts for such aggregates as the "net material product," the concept on which the published index numbers of industrial production are based is that of the "gross value of production" rather than the value added.

It is clear that the gross weighted index will give relatively higher weight to those industries the value of whose products has a relatively low "work" content and a high "material" content—"material" being defined as the input into the industry from other industries. The gross weighted index will also be influenced by the degree of integration of the system of industrial production, e.g., the combination of units into a single unit will eliminate certain products that flowed between the units and will give different weights to the various industries, as where spinning and weaving are combined in a single unit. However, changes in the degree of integration, which distort the index, can be corrected by standardizing the structure, as is done in the U.S.S.R. and Eastern European countries. In these countries the use of the gross weighted index is closely connected with the process of planning and economic control, which requires an indicator of the total flow of products.

It will be seen, from what has been said above, that the indexes of the Western countries, though conceptually weighted by value added, are in practice partly weighted by gross values. A formula which theoretically meets the problem completely, but which poses a number of practical difficulties, is as follows:

$$Q_{01} = \frac{\Sigma P_0 Q_1 - \Sigma \Pi_0 M_1}{\Sigma P_0 Q_0 - \Sigma \Pi_0 M_0} \quad \text{using base weights}$$

$$Q_{01} = \frac{\Sigma P_1 Q_1 - \Sigma \Pi_1 M_1}{\Sigma P_1 Q_0 - \Sigma \Pi_1 M_0} \quad \text{using current weights}$$

where P and Q represent prices and quantities of output, while Π and M represent prices and quantities of inputs, and subscripts 0 and 1 represent base and current periods, respectively.

Census of Agriculture.—As in the field of industrial production, the choice of an appropriate unit of enumeration for agricultural production has varied with time and place. The early censuses of agriculture in the United States (beginning in 1840) concentrated on the output of the principal crops, while in France as early as 1669, a census was taken of wool production. Even as late as 1930, the International Institute of Agriculture in promoting a world census of agriculture, stated that "perhaps the most important object to be secured by the census is an approximately accurate knowledge of the various products entering into consumption." Here again, however, the nature of production as a flow over a period of time has conflicted with the process of the census as an enumeration at a point in time. In consequence, most countries in recent years have tended to base the unit of enumeration on the productive establishments (e.g., the farm or agricultural holding) rather than on the flow of production (e.g., bushels of wheat or pounds of wool). The recommendations of the Food and Agriculture Organization (FAO) of the United Nations for a world census of agriculture in 1950 stated that the first purpose of the census was to obtain information on the number of agricultural holdings and their principal characteristics. It was assumed that crop production, in most countries, "would be estimated by multiplying the number of producing units by the average yield per unit."

The FAO program for agricultural censuses in or about the year 1960 was similarly based on the holding as the unit of enumeration and provided for the collection of information under the following headings: (1) area of holding; (2) number of sepa-

rate parcels of land comprising the holding; (3) tenure of the holding; (4) amount of arable land, land under permanent crops, meadows, pastures, woodland, and other land; (5) area devoted to each crop; (6) number of livestock; (7) number of persons engaged on the holding; (8) machinery and equipment employed. These items indicate the general practice in most countries. Over 100 separate countries and territories took censuses of this type in or about 1950. These censuses are in the main decennial censuses. Consequently, separate operations are involved to obtain annual data on the production of the main crops. Thus in the United States annual statistics of crops, livestock, prices, farm employment, and related questions are collected by mailing questionnaires to a large sample of farmers—approximately 750,000. In addition, samples have been drawn for the purpose of taking actual field measurements. Estimates based on such information are revised periodically on the basis of the data yielded by the census of agriculture. In certain other countries, such as the United Kingdom, all farms above a certain size make an annual report on each crop, thus making it possible to calculate the total of agricultural production.

It may be noted that in agricultural censuses and in current agricultural statistics there is, in most countries, no provision for the reporting of material consumed in the course of production. In consequence, the censuses do not yield a figure of net output or value added by agriculture, such as is available in the case of industry. In the same way index numbers of agricultural production usually reflect the aggregate of the output of the various crops without deduction of the inputs necessary to produce them. In this sense they are gross indexes and require adjustment to yield a figure corresponding to the contribution of the crop, or of the total of agriculture, to the national product. (See also AGRICULTURE.)

Census of Distribution.—The division of production into three classes corresponding to agriculture, manufacturing, and trade, is traditional in the United Kingdom and other countries of the Commonwealth, as well as in the United States. As early as 1691, Sir William Petty's celebrated generalization drew attention to the varying productivity of the three classes of production—"There is much more to be gained by Manufacture than Husbandry; and by Merchandise than Manufacture." The measurement of the third category of production, which is variously described as distribution, trade, or business, poses certain problems, and it is only in comparatively recent times that countries have started a series of censuses in the field. In the United States the Census of Business has been taken at intervals since 1929 but since 1948 legislation provides for a quinquennial census. Canada began decennial censuses of distribution in 1921. The United Kingdom took its first full census of distribution in 1950. In Ceylon a similar operation, entitled Census of Merchandising and Services, was taken first in 1952. These various titles all refer to approximately the same sector, namely, the wholesale and retail trade and related service trades. Altogether, more than 40 countries undertake such censuses at fairly regular intervals. In North America and the Commonwealth the censuses are separate operations confined to trade and services, but in continental Europe and Latin America they are frequently part of a larger census covering all productive establishments or non-agricultural establishments. These latter types of censuses concentrate on collecting information on the nature, location, and amount of labour employed for each establishment and have only recently tended to include questions on sales, purchases, inventories, and income generated.

The nature of this type of census is seen most clearly in the recommendations of the United Nations Statistical Commission on the subject. These recommendations state that the area to be covered should include all establishments engaged in wholesale and retail trade, business services (excluding professional consulting, accounting, and bookkeeping), motion pictures and theatres, recreation services, restaurants, cafes, hotels, laundries, barber and beauty shops, commercial photography, and other personal service. The unit of enumeration is the establishment engaged in these activities. The data to be collected include: (1) kind of business,

(2) number of persons engaged, (3) wages and salaries paid, (4) value of sales, (5) value of purchases, (6) value of stocks, (7) expenditure on fixed assets. The information on purchases, sales, and stocks permits the calculation for each kind of business, and for the economy as a whole, of the gross margins, i.e., the difference between the value of the goods and services sold and their gross cost. The gross margin is a basic figure in the calculation of the national income and product generated in the distributive sector. It, of course, exceeds the contribution of distributive establishments to the gross national product by the amount of other business costs, such as transport, advertising, accounting, and the cost of supplies consumed in the course of business.

(P. J. L.)

PRODUCTION MANAGEMENT is the process by which the physical output of a business organization is planned and the operations employed to produce the output are directed, coordinated and controlled. As production management has mainly to do with how, when and where products are to be made it is more important in manufacturing firms than in any other business organization. The techniques and methods of production management however are both widely applied. The problem of scheduling machine operations for preparation of customers' statements by a public utility, for example, may be analogous to the problem of scheduling machines for production of an item in a machine shop. The factors considered in an analysis of materials handling are basically similar, whether the site is a shop, a warehouse or an industrial plant. Likewise, choices among alternative sets of equipment for a nonmanufacturing function may be made in much the same way as they would be in the case of production equipment. While the term "production management" may be construed to take in more than "manufacturing management" and cover less than "industrial management," seldom is any clear distinction made among these labels. The following will make evident the objectives and approaches of the branch of management discussed. No particular purpose is served by insisting on one special title and rigid definition. It is convenient to refer to the management principles and practices described in the setting of the manufacturing firm and production-centred activities as production management.

Organizational Arrangements.—Production management is no more confined to a particular organizational segment within a firm than it is restricted to a particular type of firm. Because manufacturing firms frequently have production divisions and because heads of production activities frequently are given the title of production manager, there is a tendency to identify production management either as the management of a production division or as the work done by a production manager. In reality however it is unusual to find the whole of production management being accomplished by a single department; almost invariably persons other than production managers perform functions or make decisions that fall within the scope of production management.

Some management activities involved in planning what to produce and what methods of production to use are "staff" activities conducted in staff departments that are not under the administrative control of the production division. The "line" production organization is primarily concerned with performance and has the responsibility of producing output of acceptable quality, in proper quantity, at the right times and at reasonable levels of cost. Since good organizational practice dictates that authority be commensurate with responsibility, the production organization usually has the final word about the execution of plans. Where production responsibility overlaps another kind of responsibility however an

independent organizational unit may be created to handle the problems of coordination and planning that arise; or management may decree that certain decisions affecting production be made outside the division. In many firms, production-planning groups—staff agencies outside the manufacturing division—are expected to reconcile conflicting marketing and production goals such as sales division pressure for small-lot, specially designed items for favoured customers opposed by manufacturing division preference for long runs of standard products. Other specialized organizational subdivisions are frequently found in establishments where the scale and complexity of operations are such that some technical issues can best be handled by experts concentrating their efforts in a narrow field. Organizational arrangements and terminology vary, but separate departments or units may be set up for the performance of any of the following functions: product research, development and design; process development and design; specification and procurement of materials and supplies; standardization; inspection, testing and quality control; cost analysis and control; and study and preparation of work standards and methods. Usually some staff positions are created within the manufacturing division to deal with matters closely connected with its operations; other functional specialties are assigned outside the division.

To secure the advantages derivable from specialization and division of labour, the "line" portion of a manufacturing division is usually divided into departments in a way that reflects the physical organization of production. In small companies having only one plant, the functional form of organization predominates: production processes or manufacturing functions are represented individually by departments or closely related functions are grouped together to compose departments. For example, the line subdivisions in a functionally organized manufacturing division of a metal-working concern might be: (1) shipping, receiving and warehousing; (2) casting and forging; (3) machining; (4) plating and polishing; and (5) assembling and testing.

Although the functional type of organization is also found in large companies, either as the basic organizational form or within plants, some other variant is likely. For multiplant companies, individual plants may be designated as the primary organizational units of the manufacturing division; or, if several production facilities are located together, the geographical area may be made the administrative unit. Large companies with diversified product lines in some instances establish product divisions under which all operations and facilities required for production of a single product type or class of products are grouped. Product line organization is sometimes extended to the company as a whole, with a separate production department (and other line and staff departments as well) in each product division. Some manufacturing firms organize production operations according to the markets for which outputs are destined; e.g., industrial machinery, industrial materials and components, consumer products and military products. Integrated producers who perform all or several of the manufacturing processes entailed in the transformation of raw materials to finished products may organize by production stages, as extraction, transportation, refining and separating, product treatment and packaging.

The representative production organization, then, tends to be built around a line and staff structure containing components to do the staff work of advising, coordinating, controlling and providing services to line executives and departments, in addition to line subdivisions to which responsibility for the conduct of operations is delegated. In small firms, the structure is generally simple and all internal staff services may be provided by one or a few departments; in large firms, intricate administrative structures with numerous levels and a number of superimposed organizational forms can be found. Engineering functions such as product and process design, plant engineering and industrial engineering may be centralized or split among divisions; research may be divorced wholly or in part from production; purchasing and inventory control may be combined or separated, handled as part of production or not. Which production staff services are provided within a manufacturing division and which provided outside it depends on the particular company situation and history.

Functions and Problems.—The management of production may be treated in terms of: (1) the functions normally performed, (2) the problems that must be solved or decisions that must be made; or (3) both the problems encountered and the functions performed in planning, directing and controlling operations. In this discussion, emphasis will be placed on decision making because though essentially the same problems have to be solved in every manufacturing enterprise, there are many ways in which tasks can be combined in jobs, jobs grouped by functions and functions distributed to organizational units.

In the ultimate analysis, production management consists of making choices about the use of money, men, materials and time in production; i.e., production problems are simultaneously human, technological and economic. While one aspect may be dominant in a particular instance, a production decision generally involves selection from the available alternatives of an economical and technologically feasible solution conforming to enterprise objectives and subject to constraints imposed by human factors. Seldom can decisions about production be based on examination of a single factor. What is technically best can be disproportionately expensive. Capabilities of man-machine combinations and not just machines or human skills alone determine performance.

In order to reduce a review of production management problems to reasonable dimensions, some classification is necessary. At the first level a small number of general problems may be distinguished, each of which is resolvable into a series of specific sub-problems at the second level of classification. It is helpful to think of production as a system whose over-all function is transformation of sets of inputs into sets of outputs. Two kinds of processes go on in the system: the physical processes of handling and working materials for conversion of material inputs to product outputs; and the decision-making processes that govern operations. When production is viewed in this way, the general problems of production management are discerned as deciding, on the one hand what the system shall be—what physical equipment shall be employed, what methods of operation shall be followed, what form of organization and channels of communication shall exist and what rules shall be applied for making routine decisions—and deciding, on the other hand, how the system as a whole shall function at any point in time—what the quantity and assortment of output shall be, which production facilities shall be utilized and at what rates and what the composition of inputs shall be. As the solution to each of these general problems is a composite of sub-problem solutions and the functions of production management are just the things that are done to arrive at decisions and put them into effect, this discussion may move immediately to specific problems.

Forecasting.—Predictions of what products can be sold and in what quantities they can be marketed usually originate outside the manufacturing organization. Forecasting is nonetheless an important part of the production management process since production programs are shaped by expected general economic conditions, the outlook for the industry and the results of specific product market studies. While accuracy in forecasting is most vital when new products are being introduced, and especially when their introduction accompanies the launching of a new business, it is always a prime determinant of the effectiveness of production planning.

Consideration of production factors begins once existence of demand for a product is demonstrated. After the general prospects for new products are determined and before much time, effort and money are spent in developing detailed sales forecasts and plans based on them, preliminary estimates of production capability should be made: this requires answers to a number of questions. What will production costs be? Are the existing or proposed production facilities suitable for the volume and quality of output involved? What particular production problems will be met; for example, are materials available in dependable supply are there processing hazards to be guarded against, will the work force have to be expanded or given special training and will the production pattern fit with that of other products? When dealing with established products in going concerns, answers to such ques-

tions are more easily available, but the same kinds of factors must be reviewed each time production plans are formulated for an extended period. If it appears that production can be accommodated to fit general product and volume objectives, more refined sales forecasts and plans for financing, staffing, purchasing and marketing can be attacked.

When a sales forecast in its final form is delivered to production executives, its requirements—expressed as product quantities and delivery dates—must be translated into a production program. In firms that manufacture exclusively to customers' orders, forecasts may possess little detail beyond estimates of total volume and general nature of work to be expected for stages following the immediate sales period in which orders in hand are covered. Where manufacturing is performed in anticipation of sales, product characteristics are predetermined and stocks of goods are carried in inventory; sales forecasts and production will usually be in considerable detail. Preparation of the master schedule for production—which takes into account lags between production stages, inventory status in the several product lines, changing sales patterns and availability of various production facilities—by production executives and their staffs is the central planning activity in production management and the point at which the diverse elements in production are finally coordinated.

Production Planning and Control.—The importance and complexity of the task of anticipating and planning for production requirements accounts for the existence of departments of production planning and control as separate entities in manufacturing organizations. These staff groups may be assigned additional functions but their main focus almost invariably is on problems of routing, scheduling, control and dispatching.

Routing.—The routing problem is one of determining for each product to be made the sequence of operations to be performed. Each part must be routed through processes, machines to perform each operation must be chosen and the instructions to operatives of what should be done and how to do it must be written up. In plants of the type called "job-shop" where the production layout groups equipment in departments on the basis of similarity of functions and each product lot may follow a path through the layout that differs from what precedes and follows, rather complete instructions (job orders) relating to tooling, machine operation, product specifications and the like must accompany each individual job released to work. The routing sheet is the form on which most of this information is collected. In plants of the line production type where the production layout has equipment and work centres placed physically in the sequence that successive operations occur on a representative product unit and each product run follows substantially the same path, the routing has been built into the plant arrangement. While doing the original routing and layout design is a complicated job, determination and communication of the order of operations is routine thereafter.

Scheduling.—Scheduling consists of setting the times at which operations will be accomplished. When numerous orders or runs with complex routings requiring many transfers of materials during production are to be in process simultaneously, the task of arranging over-all schedules for products, operating schedules for departments and machines and schedules for supply of materials and parts is formidable. With fluctuating demands for products, it takes considerable skill and intimate knowledge of production to arrive at schedules that are both feasible and economical in view of requirements for overtime work, inventory levels, stable employment and balanced utilization of equipment.

Control.—The problem of control consists in seeing that things get done when and as planned. Quantity, quality, timing and cost are the principal controllable variables dealt with; the control process consists of comparing current progress to planned performance and initiating corrective action as deviations appear. The aspect of control which production planning and control groups are most directly concerned with is control of output through the preparation and enforcement of schedules. However, since it is often convenient to collect data on several dimensions of performance simultaneously, the report forms and procedures handled by the production control staff are likely to be multipurpose, and the

staff itself acts in a coordinating role.

Dispatching.—Dispatching, the function of issuing orders and instructions to the workplace and securing data on performance for transmission to management, is important enough to warrant identification as a separate activity in production planning and control. When only general routings and schedules are set up and some freedom is left dispatchers regarding order of work and assignment to machines and operatives, it is essential that they exercise good judgment, make fast decisions and deal with supervisors and workmen skillfully if the system is to operate satisfactorily.

Inventory Decisions.—Inventory problems are closely connected with operations planning and scheduling and, in consequence, inventory planning and control functions are usually combined with production-planning functions in organizations. Inventories in production are either planned to function as buffers between processing stages to allow their independent operation or appear as unavoidable concomitants of operations.

Inventories of raw materials are maintained to facilitate an even flow to processes as protection against interruptions of supply or because quantity purchases offer economies. The size of work-in-process inventories depends on how production is organized, the size of lots transferred between operations and the way in which schedules are constructed. Finished goods inventories are maintained so that production can be stabilized by building up inventory during slack seasons which is depleted during rush periods and so that various assortments of ordered items can be shipped without delay.

The general inventory problem consists of deciding at what points in the production system stocks shall be held and what their form and size shall be. As some unit costs increase with inventory size—storage, obsolescence, deterioration, insurance, investment, etc.—and other unit costs decrease with inventory size—setup or preparation, shortage, etc.—inventory management in part consists of determining optimal purchase or production lot sizes and base stock levels that balance opposing cost influences. Another part of the general inventory problem is deciding the levels (reorder points) at which orders for replenishment of inventories are to be initiated.

In addition to analytical problems, inventory presents problems of system design. Inventoried items must be identified, coded and catalogued so that they can be located readily when needed. Stock additions and withdrawals must be recorded so that inventory status is readily ascertainable and cost figures are kept current. Provision must be made for physical custody of inventories, storage space arrangements planned and procedures for delivering parts and supplies from stock points to work centres devised.

Facilities Problems.—Attention has thus far been centred mainly on problems of planning operations in a production system, the presence of the physical components of the system being assumed. The capacity and operating characteristics of the system, of course, are set by instrumental decisions on plant and equipment; moreover, such decisions are long-run in nature and normally result in large expenditures: they are crucial for the success of the enterprise. Initial decisions about physical facilities for production, however, are continually modified in the majority of concerns as they grow, as the pattern of output is adapted to altered marketing conditions and as need for replacement of equipment becomes apparent.

In large manufacturing concerns, decisions about the size and location of plants must be made. It is necessary to choose how manufacturing functions will be distributed among decentralized operating units and where plants will be placed in relation to markets and material sources in view of costs of transportation, plant construction and operation and factors such as climate, community attitudes, availability of utilities and presence or absence of competitive or complementary industries. The location of a factory within a selected general area and its siting so as to capture advantages of accessibility, ease of expansion and low construction cost are also significant decisions for the single-unit manufacturing firm as well as the multiplant firm.

Design of the internal arrangement of the plant and choice of the type of construction are further facilities problems to be

solved. Analysis of production requirements imposed by the attributes of the products to be manufactured usually precedes selection of a general layout as it indicates what production processes and equipment units must be provided. Limitations on space and physical arrangement are posed by the size and shape of proposed production and materials—handling equipment, the need for access to work and storage spaces and building requirements. Working within these limitations, the planners endeavour to develop a scheme of layout minimizing product flow distances in a logical, orderly, easily maintained and safe arrangement.

Process design and equipment selection normally proceed parallel with layout: the problems are simultaneously technical and economic. The technical problem is determining how desired product attributes can be created in manufacturing processes and what equipment can serve; the economic problem is deciding among process and equipment alternatives on the basis of over-all cost. The same general factors operate both in the case of original equipment selection and replacement of equipment which becomes inefficient or technically obsolete whether production, material handling or other equipment is under examination. High original costs may be justified by correspondingly high durability, increasing quality of output, ease of operation or other operating advantages. Optimal equipage must be determined in light of unit capacity, rate of operation, expected life, maintenance requirements, direct cost of operation, adaptability and versatility and any relevant special considerations.

Analytical Developments.—Because much of production management consists of contending with physical processes and variables with reasonably predictable behaviours, it always has tended to rely heavily on quantitative analysis. Viewed one way, production management is simply an arrangement for solving the classic economic problem of allocating scarce resources to relatively unlimited ends. The conceptual apparatus of economic analysis, as for example its marginal cost-marginal revenue approach, is immediately usable for production decision purposes. Cost minimization models for determining optimum inventory levels and making choices among production methods and equipment alternatives have long been used as a matter of course. Applications of probability theory in sampling inspection and process control are commonplace (see *PROBABILITY, MATHEMATICAL*). Empirical and computational approaches to scheduling, designing and operating production processes, setting work standards and laying out workplaces are part of the intellectual equipment of every competent production manager.

Developments in the field of operations research or, more broadly, in the management sciences make it possible to push the quantitative emphasis in production management even further. Mathematical programming techniques are applicable to a variety of production allocation and scheduling problems. Queuing theory is being utilized in analysis of production lines and maintenance problems. System simulation, made feasible by stored program electronic computers, is being used to study the characteristics of complex production systems with the aim of improving system designs and decision rules. As automation of production and automatic control technology continue to advance, more reliance on mathematical research can be expected. Substantial contributions to the solution of production problems are still to come from game theory (see *GAMES, THEORY OF*), organization theory and information theory.

Despite the possibility that production management and other specialized managerial functions may eventually disappear and be replaced by a "universal" management science, no immediate and discontinuous change looms. Analytical methods shown to be helpful in making production decisions will be drawn from varied sources and used; but production management will not soon become a mere package of techniques or management by formula. Production decisions are made by people in human organizations existing in a dynamic environment in which only the fact of change is constant.

PROFIT. To the businessman, profit is the monetary expression of a gain in net worth. It may be thought of as the excess of

revenue over cost during a specific period of time. Profit is often stated in terms of a percentage of sales, of revenues, or of funds invested.

In accounting for profits, most cost items cause little difficulty because they consist of actual money expenses, such as wages. There are, however, at least three exceptions. The first concerns depreciation of fixed assets, for it has to be decided what part of the original cost of long-lived equipment is to be allocated to each accounting period. The simplest procedure is the "straight-line" method, which assumes equal losses in value over the life of the asset, resulting in equal charges for each year. One doubt about straight-line depreciation is raised by the possibility that depreciation allowances will not suffice to replace old equipment when it wears out, for new equipment may have increased in price. The cost accountant is then faced with the dilemma of choosing between two principles: that of maintaining the productive organization and that of reimbursing historical cost. If he accepts the former, depreciation methods will have to be concerned with replacement problems rather than with past money outlays. Accountants have generally been reluctant to do this, since it introduces a large element of subjective judgment into the measure of profits.

Secondly, accountants face difficulties of definition and measurement with respect to stocks of goods. Large inventories may have been accumulated at different times and at different prices. Preference is often given to the assumption that the units of inventory sold are those which were acquired most recently (the "last in-first out" method), chiefly because the "first in-first out" method would exaggerate profits during periods of rising prices, and losses during periods of declining prices. If the firm's investment plans are made in response to profits, the first in-first out method will stimulate inflation, whereas the alternative method will help to dampen the cycle.

The third problem is that of capital gains. A decision must be made as to how to treat overall increases in the value of the firm's assets. As no actual revenues are derived from such capital gains unless the firm is liquidated and its assets sold, no dividends can be paid from this source. For this reason, accountants have generally chosen to disregard capital gains entirely, though economists have sometimes made much of them for analytical reasons.

Profits: in Economics.—In conventional usage, then, profits are the income of a business firm after deduction of all contractual payments from gross revenues. Closer analysis of this conventional definition raises a number of problems that continue to vex economists. It can be argued both that it includes too much and that it covers too little. It includes too much if, for example, the owner of the firm also provides managerial services, in which case part of the conventionally defined profit should properly be imputed to him as wages for those services. The term "profit" could then be restricted to the return on the capital he has invested in the firm. But, if profit is defined as the return on capital invested in the firm, it is arguable that interest payments, for example, though (unlike dividends) representing a contractual obligation, should be included in a complete measure of "profits."

On the analogy of excluding implicit wages of management from "pure" profits, one might also wish to subtract from the conventional measure implicit rent on land owned by the firm, and implicit interest on the capital invested by the firm's owners. This line of thought leads to the conclusion that in competitive equilibrium profits do not exist. For, should "pure" profits emerge anywhere, capital, land, and labour would be withdrawn from alternative ventures and put to use where their services would yield the most. The demand for all three might increase, raising interest, rents, and wages. Output would rise as a result, and prices would fall until they squeezed out all profits.

However, the real world is never one of complete competitive equilibrium. Deviations from equilibrium can emerge because (1) changing techniques of production alter the relative costs of producing various products, (2) changing consumer tastes alter the equilibrium pattern of output even with fixed techniques, and (3) competition is restricted by elements of monopoly even where

tastes and techniques are constant. Each of these disturbances can create "pure" profit.

First, the innovator who introduces a new technique can produce at a cost below the market price to earn "entrepreneurial" profits. These are likely to be temporary, lasting only until other firms adopt the same technique and new firms enter to expand output. Increased output causes prices to fall to the new level of costs. Though temporary, such entrepreneurial gains are thought to provide the incentive for technical progress in free enterprise economies. Joseph Schumpeter was perhaps the most prominent exponent of this view.

Secondly, changes in tastes may cause revenues of some firms to increase, giving rise to what are often called "windfall" profits. Windfall gains—and losses—provide the incentive in free-enterprise economies for an adjustment of the pattern of production to changing consumer preferences. Resources are shifted from industries suffering losses to industries experiencing gains. Output diminishes in the former and increases in the latter, causing prices to rise in the one and fall in the other, until once again prices just cover costs in all markets.

Finally, windfall and entrepreneurial profits can often be prolonged by monopoly control that prevents the entry of new firms into favoured markets. The aim of monopolistic control is to restrict output so as to prevent prices from falling to the level of costs (this is of course possible even in the absence of changes in tastes and techniques). When a firm restricts output, it reduces the supply of its product, contracting at the same time its demand for factors of production. The price of the product rises as a result, while input costs fall. A monopoly will seek to produce at a level that maximizes the margin between factor outlays and product revenues—at a level, therefore, that maximizes "monopoly" profits.

If entrepreneurial, windfall, and monopoly profits represent returns in excess of input costs, the difficult question arises: who appropriates them? Much ingenuity has gone into the quest for a satisfactory answer. F. H. Knight believes that at least an analytical distinction can be made between the owners of the "firm" and the owners of the production factors employed by it, including the owners of capital. If the firm's owners appropriate the pure profit (from which Knight excludes monopoly returns), it must be in return for activities which no one can be hired to perform. The bearing of risks may be such an activity, if risk is defined in a very special sense. It cannot be connected either with chance in gambling or with hazards that can be insured against. Knight settles on risks that produce change or adaptations to change—"entrepreneurial" risks, as he calls them.

Less subtle economists have found it difficult in practice to distinguish between the owners of the firm and the owners of the equity capital invested in it, especially since the returns on risk-bearing are quite commonly appropriated by the investors of that capital. As a result, the existence of monopoly profits, for example, may exert upward pressure on interest rates, at least in the long run. Similarly, should windfall profits persist over a sufficiently wide range to be positive for the economy as a whole, they too would affect interest rates; so would recurring entrepreneurial profits. The conclusion has therefore been drawn that among the determinants of the return on capital, including contractual interest. A satisfactory and complete theory of profits would therefore have to explain the entire return on capital.

The question of what determines this return is an extraordinarily difficult one to answer. Many economists reason as follows: where land and labour are scarce, competition among capitalist employers is likely to bid up payments to landowners and workers, as long as the payment for an additional acre or worker is less than the addition to output and revenue which additional employment creates. Such competition will leave a residual income for the capitalist only if the contribution to output diminishes with each additional acre rented or worker hired. For their wages and rent cannot rise above the output of the marginal acre or worker, even though earlier ("intramarginal") factors produce more. Their excess output is appropriated by the owners of capital. But

not all economists are equally sure that diminishing returns operate with capital. If the doubters are right, another explanation for interest—and for profit—must be found. See CAPITAL AND INTEREST; LABOUR; RENT; see also references under "Profit" in the Index.

(H. O. Sc.)

PROFITEERING, a term that came into use during World War I when it was generally applied to the actions of individuals or firms who made unreasonably large profits during a national emergency. It usually carried the connotation that the recipient of these profits had acted improperly in obtaining them. Although the term has been used most frequently in connection with war-time situations, it is applied during other types of emergencies as well; e.g., excessive inflation. While the word itself is comparatively new, it describes an old phenomenon. During every war, some individuals and firms have made inordinate profits, particularly those producing and selling munitions.

Numerous situations make profiteering possible. For example, an embargo may shut off the supply of certain articles, enabling those who hold supplies of them to sell them at high prices, or the government may suddenly and substantially increase its purchases of scarce materials, bringing about a similar result. The history of profiteering and its sequel, antiprofitteering legislation, discloses continuous public concern with the problem and greater refinements in the devices employed to eliminate it.

United States.—During the American Revolution the continental congress recommended to state legislatures that they regulate the prices of commodities and services in view of the "spirit of sharpening and extortion . . . being confined within no bounds." Most of the state legislatures responded with laws that regulated the price of practically every commodity as well as wage rates. One of these laws was directed against the "wicked arts of speculators, forestallers, and engrossers, who infest every corner of the country."

During the Civil War, government suppliers often received higher than market prices for their goods. One supplier might have been preferred over another because he had hired an influential representative to deal with the government. An attempt to prevent such conduct was made by changing the procedures for awarding and checking on contracts. Contracting officials were required to advertise all contracts they proposed to award, where this was practicable, and new criminal statutes to eliminate bribes of public officials were enacted. In addition, a special commission was established to review certain contracts in connection with the awarding of which improper dealing was suspected. This commission had no power to require adjustment of contracts but the publicity given to these transactions persuaded some contract holders to agree voluntarily to accept lower prices than those for which they had originally bargained. No attempt was made during the Civil War, however, to eliminate profiteering which took place outside the area of government contracts or to control prices and the profits received under government contracts.

Before the Spanish-American War, congress for the first time sought to limit the profits of defense suppliers directly when it imposed a maximum price at which armour plate might be purchased by the navy department.

The outbreak of World War I increased the demand for United States goods. When the U.S. entered the war in April 1917, prices had risen 70%; there was also a sharp increase in corporate profits. Before the U.S. entered the war, congress made no serious effort to limit profits, confining itself in this regard to a special tax of

12½% on profits from the production of munitions and an 8% over-all excess-profits tax. After the U.S. entered the war several devices were employed in an attempt to eliminate what was then called profiteering.

First, a new kind of contractual arrangement was evolved. The profits of defense suppliers could not be controlled merely by requiring competitive bidding because as prices of raw material and labour began to rise rapidly contractors refused to take fixed-price contracts. In an effort to protect suppliers against the risks of unanticipated costs and the government against excessive prices, the government began to negotiate contracts under which the supplier was paid his actual costs plus a fixed percentage of such costs. It soon became apparent that this type of arrangement stimulated the supplier to increase rather than decrease his costs of performance and was potentially more costly to the government.

Second, congress and a variety of administrative agencies established maximum prices for certain commodities: basic raw materials and fuels, munitions of war and general consumption necessities. In general, profits were not considered to be sufficiently regulated by this method and a third device, the excess-profits tax, was ultimately relied upon as the principal method of eliminating excessive profits during World War I. The first such tax was imposed in 1916. The rate of tax upon excess profits was increased in subsequent years until it reached 80% in 1918. Although over-all profits of corporations declined in 1918, individual companies, especially those engaged in supplying the government directly, were able to make what were regarded to be abnormal profits despite the measures just described.

While profiteering was doubtless curtailed by the more aggressive controls of World War I, it was by no means entirely eliminated. During the period between World Wars I and II there was a continual outcry against the war profiteering that had taken place. It was even contended that by their desire for profits, munitions makers had helped bring about the war. The American Legion backed various bills to limit war profits and in 1924 the platforms of both the Democratic and Republican parties contained planks for the control of profits from war production.

The first positive action in this area was taken by congress in 1930 when it established a commission to investigate methods of equalizing the burdens of war and determine how war profits could be eliminated: this commission recommended a wartime excess-profits tax of 95%. In 1934 the Nye committee of the senate began hearings to investigate the munitions industry. The committee recommended such measures as the nationalization of the peacetime munitions industry and the imposition of a wartime tax of 99% on personal incomes over \$20,000 as well as an excess-profits tax on corporations. Although congress proceeded more moderately, it did take a step in the direction of eliminating large profits from defense contracts when it enacted the Vinson-Trammell act in 1934. This law, as amended and supplemented in the following years, limited the maximum allowable profits of airplane and vessel builders and certain of their suppliers to a percentage of the contract price: the allowed profit was 10% and 12% depending on the type of article involved. This limitation was suspended in 1940 in favor of an excess-profits tax of 90% on all corporations, whether or not they were government suppliers. While this bill was designed primarily to raise revenue, it sought to achieve this by distributing the burden of national defense in a manner calculated to prevent profiteering.

With the entrance of the U.S. into the war in 1941 and the attendant expansion in munitions production, the concern over profiteering mounted. Congress initially used an approach similar to that employed in the suspended Vinson-Trammell act. It considered limiting the profit-cost ratio of munitions makers to 6%. While such an approach doubtless would restrict profits, it discouraged rather than encouraged reduction of costs and production of the most effective munitions in the most economical manner. A far more satisfactory device was the "cost plus a fixed fee" contract employed extensively by the armed services.

Another device—renegotiation—was introduced in World War II to control profiteering. Renegotiation involved an annual review by the government of a supplier's profit after the perform-

ance of his contracts and the refund by him of portions of his profit that the government regarded as excessive under all the circumstances. The advantage of this procedure was that it provided a spur to efficiency since, in theory, the efficient producer might retain more of his profits than the inefficient producer.

Two other devices were employed to eliminate profiteering during the war: one was the excess-profits tax, already discussed; the other was price control. The Office of Price Administration was established in 1941, "to prevent spiraling, rising costs of living, profiteering, and inflation resulting from market conditions." The OPA imposed maximum prices on most commodities and services other than those sold to the military departments.

The activities of the renegotiation and excess-profit authorities suggest in some measure the extent of profiteering that occurred during the war. From defense expenditures of over \$190,000,000,000 that were subject to profit control, renegotiation led to the direct recovery by the government of over \$10,000,000,000. Additional amounts estimated at about \$4,500,000,000 were refunded through voluntary adjustment of contracts by firms subject to renegotiation. The government also recovered from the defense and nondefense sectors of the economy about \$16,000,000,000 in excess-profits taxes.

In 1948, when the nation embarked on unprecedented peacetime expenditures for defense, profit controls in the form of renegotiation were reinstated, principally upon aircraft manufacturers and some of their suppliers. In 1950, after the beginning of the Korean War, profiteering again became a matter of major concern and a series of laws was passed by congress. The Defense Production act of 1950 conferred authority upon the president "to prevent profiteering." A new excess-profits tax law was enacted whose main purpose was the raising of revenue by assessing those "corporations whose profits are higher than they probably would have been in the absence of hostilities and a large military budget." Finally, in March 1951, a new renegotiation act was enacted which applied to most defense contractors and suppliers.

The first two laws ceased to be effective in 1953; as early as 1952 congress directed that price regulations be suspended immediately in cases where no inflationary pressures existed. The excess-profits tax lasted only a short time after the end of hostilities in Korea. Only the Renegotiation act of 1951 which applied solely to profits from defense contracts was continued although its scope was gradually whittled down so that its main impact was on the aircraft and space industries.

Great Britain and Europe.—As in the United States, profiteering in England and on the continent is an old phenomenon; the legislation enacted to combat it is perhaps the best evidence that the profiteering existed. Price control laws are found as early as the 4th century in the Roman empire. In 1793, while France was being blockaded by the British fleet, the French government passed the "Law of the Maximum," which fixed prices for grain and other commodities with reference to 1790 prices and set wages at a level of 50% above those of 1790. In England prices and wages were regulated from time to time from the 14th century.

Beginning in the mid-19th century, army purchasing procedures in England were centralized and tightened in an effort to eliminate profiteering; however, these procedures had to be loosened at the beginning of World War I when it became necessary to purchase uncommonly large amounts of supplies within a short time. Among other things, competitive bidding for contracts had to be abandoned.

As soon as purchasing controls were relaxed, much criticism developed concerning speculation and profiteering in war contracts. As a result, the government took over production of many munitions; it also adopted new contracting procedures in connection with the defense production performed by the civilian sector.

Among these was the use of the target cost contract: this prescribed in advance a target cost of production and provided that if the costs actually incurred by the contractor were below this figure, then a share of these savings was to be paid to the contractor along with his actual costs and the profit previously agreed upon. The virtue of this type of contract as compared to the traditional fixed price was that it prevented a defense supplier from

profiteering and at the same time gave him an incentive to produce as efficiently as he could.

The British government also began in 1915 to tax excess profits being generated from the war. This form of profit control spread rapidly to other parts of the British empire and all of Europe. In addition to these relatively new devices to combat profiteering the British government employed the old device of price fixing; by 1916 the maximum price of several commodities was being prescribed by the government.

The excess-profits tax was continued in England for a short time after the war; price fixing was not only continued but reinforced by the Profiteering act of 1919. Under this law, which was the first to include the term "profiteering" in its title, the Board of Trade investigated the prices of many commodities and the profits derived from dealing in them; it then issued reports reflecting the results of its investigations. The act lapsed in 1921 before it accomplished a great deal; the problem of profiteering to which it had been addressed ceased to exist as soon as unfavourable economic conditions began to push the price level downward.

The inflation which raged in Germany in 1923 resulted in the establishment of a cartel court which had the responsibility of bringing about reductions in and preventing increases in prices when profiteering seemed to be taking place. During most of the interwar period in Europe profiteering was not a matter of great concern; rather, during the great depression there was the apprehension that profits and prices were not adequate for the proper functioning of the economic system.

As soon as World War II began there was again a preoccupation with profiteering. Germany began the war with a thoroughgoing system of price control which at first sought to hold prices and wages at 1936 levels and which required justification for any price increases or for the maintenance of prices that appeared to be yielding excessive profits.

Bitter memories of World War I and its aftermath reinforced the resolution of the government in Great Britain as well to prevent windfall gains from arising as the result of the war. In 1939 the Price of Goods act was enacted to fix prices at levels designed to freeze sellers' incomes at prewar levels. This act and the Goods and Services act passed in 1941 prevented undue price rises at the retail level but was largely ineffectual at the manufacturer's level. The difficulty was that it was necessary to leave prices high enough to provide an incentive for the production required for the prosecution of the war. This meant that the low-cost producers frequently earned high profits; accordingly, the attack upon profiteering in this area had to be made from another direction.

In general an attempt was made to set firm prices on contracts; however, in order to minimize profiteering the government in many cases postponed the establishment of a firm price until production was well advanced and cost experience had been gained. The objection to this was that, to the extent that the price finally was based upon realized costs, the contractor had no incentive to keep down his costs. An attempt was then made to use target cost contracts as in World War I in order to restore this incentive, but it was usually as difficult to negotiate a realistic target cost in advance as it was to negotiate a fixed price. Ultimately, a choice had to be made in connection with each purchase between the fixed-price contract with its inherent risk that excessive profits would be realized by some contractors and various types of contracts under which the supplier's compensation was determined primarily with reference to actual costs incurred by him.

In general there was no attempt to recapture excessive profits from prime contracts after they were realized, as renegotiation did in the United States; however, an informal procedure resembling renegotiation was instituted with respect mainly to subcontractors. They were required to submit periodic over-all trading reports which disclosed the profits they had made from defense contracts; they were required to refund that portion of their profits considered by the contracting agency to be unreasonable. By 1948 some £57,000,000 had been recovered in this manner from several thousand contractors.

Beyond all this, an excess-profits tax was imposed which, after May 1940, was at the rate of 100% and which was computed with

reference to profits earned from 1935-37. Parliamentary concern with the question was so great that the adoption of this extreme remedy against war profiteering did not result in the discontinuance of the other efforts to prevent excess profits.

After the end of World War II, most of the wartime controls over prices and production were maintained because of shortages. Food rationing did not entirely cease until the summer of 1954 and some price controls lasted longer. Other measures directed against profiteering, however, lapsed at the end of the war.

PROFIT SHARING, a system by which, in accordance with a scheme defined in advance, employees are paid a share of the profits of the business enterprise in which they are engaged. The way in which profits will be divided between stockholders (shareholders) and employees is prescribed in advance and the amounts distributed vary from year to year according to the profits actually earned.

As far back as 1889 an International Congress on Profit Sharing, held in Paris, defined profit sharing along these lines, specifically stating that payments must be made in accordance with a freely agreed scheme and must consist of a share, determined in advance and not variable year by year at the discretion of the employer, of the profits of an undertaking to a substantial proportion of its ordinary employees. These payments are distinct from and additional to wages, which are generally paid at rates current in the industry and locality. By the requirement that schemes must be defined in advance, profit sharing proper excludes gifts, gratuities, or other payments made by an employer to his employees out of profits at his discretion without being bound to do so. An employer is usually free to terminate a profit-sharing scheme at any time, but until he does so he has bound himself to observe its provisions. The Paris definition excludes schemes in which a share in profits is paid only to a small number of persons in administrative and technical positions and not to manual workers.

Since the payments must be related directly to profits, systems based on production bonuses, individual or group piece rates, or other methods of payment related to output are not profit-sharing systems. Similarly, arrangements by which the total production or gross proceeds of an undertaking are divided in predetermined proportions—for example, by share fishermen, and in some forms of land tenure, as sharecropping or *métayage*—must be excluded, since something other than profits is being shared. On the other hand, if employees are given shares in the capital of the undertaking in which they work, or if such shares can be acquired by them on specially favourable terms, such schemes can be regarded as a form of profit sharing.

Early Examples.—France can claim to have been the pioneer in profit sharing, several plans having been started there before the middle of the 19th century. The earliest known example was that introduced in 1820 by the French National Fire Insurance Company; in 1842 the Paris firm of E. J. Leclair, house painters and decorators, started a scheme which attracted wide attention in France and abroad. During the next few decades other French firms started profit-sharing plans, some of which were highly successful, as for example, those introduced by Godin of Guise and by the Bon Marché store in Paris.

UNITED KINGDOM

Development of Profit Sharing.—The French schemes attracted considerable interest in England about the middle of the 19th century, and their principles were advocated particularly by the Christian Socialists, who influenced cooperative societies to apply them to their employees. Later the cooperative movement developed along somewhat different lines, and most of the

consumers' cooperative societies and cooperative wholesale societies ceased to practise profit sharing, though the system was retained by some cooperative production societies especially in the boot and shoe industry and in clothing, printing, and building.

Outside the cooperative movement the first important scheme was that of Henry Briggs, Son and Co., Ltd., a firm of Yorkshire colliery owners, which introduced profit sharing in 1865. At first the scheme was very successful, but the directors ended it in 1875 because their employees took part in a strike for higher wages. Between 1880 and 1910 about 240 schemes are known to have been started; most of them were straight profit-sharing arrangements, but some took the "co-partnership" form (*see below*). The rate of growth was much greater between 1910 and 1920 when big wartime and early postwar profits were being earned. More than 200 were started in this decade. After the onset of depression in 1921 fewer schemes were started, but the number was still around 140 in the 10 years to 1930. During the depression years of the 1930s still fewer were started. However, during the interwar years more were soundly based, as there was better knowledge of what was involved. Some of the earlier plans were based on wrong motives and unsound methods, and about 85% of those started before 1900 had been discontinued by 1930, many of them having lasted only from 10 to 20 years. A few, however, were still in operation in the mid-1960s.

On the basis of Ministry of Labour statistics, it is estimated that more than 400 companies in the United Kingdom in the 1950s and early 1960s had profit-sharing schemes on a prearranged basis. The number of participating employees has been about 500,000 or approximately 2% of the total number of persons employed in British industry (excluding those in the nationalized industries, professions, and central and local government services in which profit sharing could not be applied). In addition to these companies, others had arrangements that were broadly profit sharing in practice but paid bonuses arbitrarily in prosperous years instead of on a predetermined basis.

Profit sharing is most widely applied in the chemical industry. In most other industries there are some profit-sharing companies, though they never form more than a small minority. Until after World War II the biggest development was by the gas companies, especially in the London area. This began in 1889 when the South Metropolitan Gas Company introduced a scheme by which employees were paid a cash bonus varying with the profits of the company. After revision the scheme took the form of "co-partnership," half the bonus due to the employees being used to buy for them ordinary shares of the company and the other half accumulating with interest but with the right of withdrawal by the workers in special circumstances. Finally, in 1920, the scheme was made statutory by legislation which provided that surplus profits, after payment of prescribed basic rates of dividend on capital, were to be divided in the proportion of three-quarters for the benefit of consumers by reducing the price of gas, and the remaining quarter in equal parts to the ordinary stockholders by increasing their dividends and to the employee co-partners as a percentage bonus on their salaries and wages. As before, half the bonus was capitalized and the other half invested subject to exceptional rights of withdrawal. Nearly all the leading gas companies and many of the smaller ones introduced similar schemes, which proved highly successful and resulted in large amounts of the capital of the companies being owned by the workers. These schemes, however, were terminated, with compensation, by legislation passed in 1948 to nationalize the gas industry.

In the years of prosperity immediately after the middle of the 20th century, increased interest in profit sharing and co-partnership was shown by certain leading firms, and both the Conservative and Liberal parties favoured the adoption of schemes as a means of promoting better industrial relations. The biggest company to introduce profit sharing during the 1950s was Imperial Chemical Industries, Ltd., which announced in 1954 a plan that by 1957 covered 91,014 out of 115,834 employees. The scheme provides for payment of annual bonuses to adult employees with two and one-half years' service or more. The total amount of the bonus is 22% of the amount paid as interest or dividends to

the company's stockholders, but no bonus is paid if the dividend for ordinary shareholders is less than 5%. The bonus money is distributed to eligible employees in proportion to their total annual remuneration. The bonuses are invested in the ordinary stock of the company at the current market price and held by trustees until an employee has a minimum of £40 of stock to his credit, when it is turned over to him without any restriction. The directors have power to amend or terminate the scheme.

Types of Schemes.—Schemes of profit sharing vary widely, since they have mostly been devised on the initiative of individual firms to suit their own conditions. Some undertakings are in process of growth while others have reached stability; some are in industries which experience wide fluctuations in prosperity and need to set aside bigger reserves in good times to meet periods of depression than are required by undertakings in industries which enjoy steadier demand; and some undertakings have much higher labour costs in relation to total cost than others.

Schemes fall into three main categories: (1) profit sharing alone; (2) employee share ownership with participation in management; and (3) shareholding with some form of co-partnership. Some schemes are a combination of the first two kinds or of the first and the last.

Profit Sharing.—Schemes of profit sharing usually provide first for payment of all working expenses, amounts necessary to cover depreciation and reserves, interest on debenture stock and preference shares, and a specified percentage, often 5 or 6%, as dividend to ordinary shareholders. Then employees entitled to participate receive a defined share of any surplus profit. An alternative is to distribute to employees an amount not exceeding a specified sum, say £50,000, the remainder of the surplus being paid in additional dividends to the ordinary shareholders. One variation is for one-half of surplus profits to go to the employees, one-tenth to the management, and two-fifths to holders of ordinary share capital. Where capital costs are high, proportions down to one-tenth of surplus profits may be distributed to the employees.

Most schemes lay down a qualifying period of employment in the firm, often one year, but some require several years and others only three months. Bigger shares are sometimes provided according to length of service. Participation is sometimes restricted to adults in manual and similar grades; in other cases juvenile workers receive lower rates of payment than adults. Some schemes pay higher rates to managerial and other salaried staff than to manual workers, on the ground that salaried staff have a bigger influence on the amount of profit.

Surplus profits are usually divided on the basis of each participant's wage or salary. This ensures that persons will share in profits roughly according to their value to the firm, the skilled workers receiving more than the unskilled. The amount a worker receives varies considerably from industry to industry, from company to company, and from year to year. A frequent rate, however, has been about 6% of earnings (roughly the amount a worker would earn in three weeks).

In more than two-thirds of all British schemes of profit sharing and share ownership the share of profits is paid in cash or is credited in a savings account. Nearly one-sixth of all schemes consist of the issue to employees of shares in the company on specially favourable terms or provide for the payment of dividends varying with profits on deposits made by employees. In a few schemes the amounts due to the workers are paid into a provident or superannuation fund.

Share Ownership.—Employees of a company can buy its shares on the stock exchange, but some firms have made available special shares which can be obtained only by their employees. There is great variety in these schemes, but each is a method of saving and is intended, like profit sharing, to give employees a better understanding of the economic and financial problems of the firm for which they work and to increase their interest in its success. Some schemes combine profit sharing with share ownership by providing that all or part of the amount due to an employee may or shall be invested in the firm's shares. Alternatively, shares in some schemes may be bought by installments paid out of personal savings, often by deductions authorized by the worker from his

wages. The shares may be sold to employees at par, at market price, or under market price.

These schemes, which enable employees to accumulate substantial amounts in shares over a period of years, usually last longer than profit-sharing schemes in which only cash bonuses are paid. Dividends on employees' shares are usually at the same rates as on ordinary shares, but some companies issue special preference shares, with a specified rate of interest (e.g., 6%), and these shares may or may not receive additional interest if dividends beyond a given rate are paid to ordinary shareholders.

Restrictions are usually imposed on the holding of special shares, but many companies also provide safeguards to maintain the value of the special shares issued to employees. In many cases the shares must be returned to the company if the employee dies or leaves the company's service. Some companies pay the market value when such shares are returned, but many pay the par value. This protects these savings of employees against loss but reduces the value of the scheme as an education in the risk run by investors. The employee holders' dividends vary with changes in the firm's prosperity, but their capital is safeguarded against the effects of such changes. One argument for such a safeguard is that employees holding special shares are not free, as are ordinary shareholders, to sell their shares whenever they wish and thus cannot exercise their judgment when to sell so as to make a capital profit or avoid a capital loss (see also EMPLOYEE STOCK OWNERSHIP).

Co-partnership.—Co-partnership between employers and employees implies some participation by the employees in the management of the business. This may range from consultation in works councils or joint production committees to the rights of employee shareholders to attend and vote at annual and other general meetings of shareholders and to elect employee representatives to the board of directors. An increasing number of companies regularly give their employees information about the economic and financial position of the business, its problems, policy, and prospects. In many firms, representatives of the employees take part in the management of welfare and social activities. These methods give employees greater influence on the business in which they work and raise their status.

Only a few schemes provide for employee shareholders to be represented on the board of directors; even then their representatives are in a minority and their influence is usually small because they lack adequate experience of the economic, financial, and technical problems of the business. In these schemes, only those employees who have had considerable service with the firm (e.g., ten years) and who hold a specified minimum number of shares can be nominated for election as directors.

Attitudes of Employers.—The fact that, after a century during the larger part of which there has been active publicity in favour of profit sharing, not more than about 900 British companies have adopted it, and that about half of this small minority of companies discontinued it within two or three decades, is a clear indication that the great majority of employers have not been attracted by profit sharing. Most employers point out that they pay their employees current rates of wages and that in periods of prosperity workers gain higher wages and thus share in prosperity. Profits should, in their opinion, accrue to those who undertake the financial risks of the business. Some argue that if employees share directly in profits they should similarly carry directly a part of the burden in years when losses are incurred. Many do not regard profit sharing as an appreciable incentive to greater effort, especially as those employees who work harder receive only the same share as those who make no greater effort. They claim that there is no satisfactory way of measuring what increase in output results from profit sharing. Against this, however, several hundred employers whose schemes have worked successfully, while not claiming that they can measure results in terms of increased output, are satisfied that profit sharing leads to better relations with their employees, who feel that there is social justice in participating directly in profits to which they have contributed by their labours.

Attitudes of Trade Unions.—Trade unions have been generally hostile to profit sharing and co-partnership, partly because,

in the early days, some employers used them as a weapon against the unions. The workers were told that they would gain more from these schemes than from action by trade unions to raise wages. Also workers in some firms were warned that the profit-sharing schemes would be terminated if they went on strike. Trade unions have feared that profit sharing would strengthen the loyalty of workers to their firm and weaken their interest in the trade-union movement. The policy of trade unions is to gain the best possible general level of wages and working conditions for their members, and the unions have worked to secure standard rates of wages throughout an occupation or industry. With profit sharing the workers' incomes would vary from firm to firm according to the profits of each. British unions are not concerned with special differential advantages for employees who are fortunate enough to be employed by firms here and there which are exceptionally prosperous. Also, as profit-sharing schemes are usually introduced on the initiative of employers, the workers receive benefits which the unions have not won for them. The unions have found no method of regulating profit-sharing schemes by collective bargaining agreements.

However, the former hostility of trade unions changed somewhat in the interwar years and after World War II, the attitude becoming one of indifference or mild acquiescence. This was largely because employers ceased to use profit sharing as a weapon against the trade unions but tended instead to discuss schemes with their employees and often with trade-union representatives before introducing them. The greater strength of the unions would enable them to oppose successfully the misuse of profit sharing by employers.

Value and Limitations.—Those employers who have introduced profit sharing because they believed their workers would be stimulated to greater effort and that output would rise appreciably have been disappointed. This has been largely because profits depend upon many factors in addition to the efforts of the workers; for example, the efficiency of management and the market demand for the product. As an inducement to greater production by the workers, the relationship between effort and reward is not close enough. Profit sharing is much less effective as an incentive than systems of payment by results where remuneration is directly related to the efforts of a worker, and where he receives his reward with little delay instead of having to wait until after the annual general meeting of the company. During periods of depression when profits have been small or nonexistent, schemes have foundered because they ceased to interest either employers or employees. A scheme may be sponsored by an employer who has faith in profit sharing and operates it successfully, but the firm may later come under new management unfavourable to profit sharing and the scheme is terminated. Even the success of some schemes has resulted in their being discontinued; for example, companies with stable profits have frequently distributed amounts which varied so little from year to year that the share in profits has finally been used to increase rates of wages instead.

Profit sharing provides only one among many ways of promoting good relations in industry. The most successful schemes have been those in companies where profit sharing with or without partnership has formed part of a comprehensive program for promoting good will. Applied in this way, profit sharing and co-partnership can strengthen the mutual interest which capital, management, and labour have in the efficient running of the undertaking, ensure a better understanding by the employees of the economic problems of business enterprise, broaden the basis of capital ownership, and raise the status of employees. (J. H. RN.)

UNITED STATES

History.—Before 1942 profit sharing did not assume major proportions in the United States. Though experiments with it had begun as early as 1867, only 50 plans were known to exist in 1896 and only 12 of them remained in operation until 1916. C. C. Balderston's study, published in 1937, found only 67 plans in active operation. Labour unions were opposed to profit sharing for several reasons: they were suspicious of the bookkeeping procedures used in determining profits; they looked upon profit shar-

ing as a clever device used by employers to attach employees to their companies and weaken the appeal of unions; they thought that profit sharing would lead to the "speedup" and would be incompatible with collective bargaining. But by the 1960s labour's attitude had changed somewhat and a substantial proportion of the employees covered by profit-sharing plans were in unionized plants. One of the major reasons for this change was the new federal tax policy adopted during World War II. In 1942 the Internal Revenue Code provided that employers' contributions to profit-sharing funds collected and disbursed as specified in the code were deductible expenses for purposes of taxation. With wage and salary rates practically frozen during the war many employers saw in tax-deductible contributions to profit-sharing funds a means of supplementing employees' wages and decreasing labour discontent. For concerns in excess-profit brackets only about 15% of each dollar set aside for profit sharing was a net loss to the company; the other 85% came out of money which would otherwise have been paid as taxes.

In addition to the value of the contributions and the investment earnings of the reserve fund to their credit, employees stood to gain from the fact that when they received the annuities to be paid to them after they retired, they would pay taxes only on the reduced income they would then be receiving. In other words, they would be in a lower income bracket than they were during the years when the fund was being accumulated.

An employer was not permitted by the federal tax code to deposit to the credit of an employee in any year a sum greater than 15% of the employee's wages or salary during that year. Moreover, the employers' contributions had to go into trust funds for deferred benefits. They could not be paid to employees as current cash income. The plan had to be for the exclusive benefit of employees and their beneficiaries, had to be put into written form and its provisions made known to the employees, and, specifically, could not be a device to increase dividends of stockholders or to distribute more of the profits to officers of the company and supervisory employees.

Prevalence of Profit Sharing.—A substantial growth in profit sharing occurred after 1942. The National Industrial Conference Board survey in 1946 revealed that plans were reported by 401 companies out of 3,498 questioned, an increase from only 158 out of 2,700 companies studied in the 1939 survey. The Bureau of Internal Revenue reported that up to Aug. 31, 1946, it had processed 2,508 profit-sharing trust plans for establishments employing 1,312,226 persons (*cf.* NICB report no. 97, p. 5). How many of these were actually put into effect and how many were actual profit-sharing plans is not clear. Between 1947 and 1951 about 350 concerns joined the Council of Profit Sharing Industries, which had as its objective the promotion of sound, well conceived profit-sharing plans. The idea entered the automobile industry in 1961 when the American Motors Corp., one of the smaller producers, adopted a profit-sharing plan. A survey of a representative sample of small and medium-sized companies published by the Profit Sharing Research Foundation in 1964 concluded that the number of U.S. companies sharing profits with all or some of their employees lay between 85,500 and 145,900.

Cash and Deferred Payment Plans.—Profit sharing may take the form of periodic (usually annual) payments in cash or deferred payments, usually retirement annuities, out of a trust fund accumulated over many years through employer contributions credited to each employee and invested for his benefit by the trust fund. The Profit Sharing Research Foundation reported in 1954 that among 300 companies studied intensively, cash plans predominated among small companies, deferred plans among large companies, and plans that combined cash and deferred methods characterized middle-sized companies. Two factors account for the favour of the deferred plans among large companies. These concerns became more interested, and so did unions, in providing wage earners with lifetime economic security. And they wished to take advantage of the 1942 tax provisions. To do so their profit contributions had to be paid into a trust fund from which their employees would draw annuities in later years. The smaller companies liked plans under which they could pay employees

their shares of profits annually in cash or company stock because it is simpler, and perhaps safer, for them to pay off their obligations annually rather than to handle the complexities of long-lived trust fund retirement plans. Sears, Roebuck and Co., through a deferred payment plan started in 1916, built up a trust fund valued at about \$350,000,000. The company contributed 45%; the employees 15%; and interest, dividends, and appreciation in the value of Sears, Roebuck stock contributed the other \$118,000,000 to the fund. While the government restrictions were largely removed after the end of the war, interest in such deferred payment plans continued at a high level.

Mortality of Profit-Sharing Plans.—The death rate of profit-sharing plans was high during most of the period after their introduction in the United States. There were many reasons for this state of affairs. Employers, who hoped that profit sharing would keep unions out of their plants or cause employees to be more "loyal" to their employer, that it would make employees work harder, prevent employees from going on strike, or even reduce labour turnover, were often disappointed in their expectations.

Industrial depressions also wrecked many plans. When employees fail to receive benefits to which they have become accustomed, it is hard to convince them that it is because the employer cannot make the payments. Employees' good will, co-operation, or loyalty are not bought by a profit-sharing plan. Experience seems to indicate that where employers have discussed fully and continuingly with their employees the essentials of profitable business operations and have based their profit-sharing plans upon mutually shared understandings and objectives, the plans have been more likely to succeed.

The National Industrial Conference Board reported that of 202 companies which had profit-sharing plans in 1937, 35 or 17.3% had discontinued them by 1947. The board also found that the ratio of discontinuance was ten times as great among the current distribution plans as among the deferred plans. Nearly two-thirds of the plans discontinued had been operating for more than five years.

Leaders in the profit-sharing movement became aware of the fact that the successful management of profit sharing requires as careful attention to principles and techniques as other aspects of business management. The success of profit sharing depends upon such factors as: (1) the skill with which an employer establishes good understanding of the plan among his employees; (2) the amounts and types of employer contributions; (3) the rules governing employee eligibility; (4) whether employees must or may contribute to a deferred plan fund; (5) the method of allocating benefits to employees; (6) whether employees shall have a vested right to the amount of the fund credited to them personally; (7) whether employees shall have a right to withdraw their shares if they take employment with another company; (8) frequency of payment under cash plans; (9) what percent of the company's net profits shall be set aside for stockholders before any of the profits shall be available for profit sharing; (10) how and by whom the plan shall be administered; and (11) how employees' shares shall be computed. (D. D. L.)

OTHER COUNTRIES

In most of the countries of Western Europe, including France, Germany, Belgium, the Netherlands, Switzerland, and Italy, profit sharing has been adopted by a small number of firms, but relatively fewer than in Great Britain and with fewer participating employees. Among these countries the greatest development is in France, where the biggest application is by insurance companies, some of which have had plans in operation successfully for more than half a century. Among the few plans in Germany which have had a long life, the best known is that of the Zeiss firm of optical glassmakers. In European countries co-partnership is rare, most of the plans providing that the share of profits due to employees shall be paid to them in cash or as credit in a savings fund. There are a few profit-sharing schemes in Australia, and also in New Zealand where the Employee Partnership Institute has undertaken propaganda for co-partnership.

Profit sharing is required by law in Venezuela, and large amounts

are paid annually to employees by the bigger firms, including the oil companies. The law provides that specified proportions of profits shall be shared with employees up to a maximum equal to one month's wages in small firms and two month's wages in large firms; the proportion ranges from 2.05% of profits in small firms to 12.45% in large firms. In certain other Latin American countries, including Chile and Peru, laws have been passed making it compulsory for firms to pay a share of profits to employees. In India and Pakistan many companies, particularly expatriate companies, pay substantial annual bonuses more or less related to profits.

PROGRAMMED LEARNING (PROGRAMMED INSTRUCTION) is an educational technique in which the material to be learned is organized and presented in a format permitting self-instruction and self-testing and enabling the student to learn at his own pace with a minimum of formal instruction. The idea behind this technique is that many subjects may be learned best when they are presented in small steps that most students can easily master one at a time in sequence, the successful completion of each step providing its own reward (or incentive) in the form of a sense of accomplishment. It has four important characteristics. First, it recognizes that learning is a form of behaviour. Second, the subject matter, instead of being arranged on the basis of logic, is organized in a psychologically coherent sequence, or program. Third, the student is required to make an overt response at each step in the program by writing something, pushing a button, moving a lever or performing some other physical act. Fourth, the student immediately knows whether his response is correct. The program is broken into items or frames of information comprising a sequence or sequences through which the student must work.

Programmed instruction received its major impetus from a paper, "The Science of Learning and the Art of Teaching," published in 1954 by B. F. Skinner in the *Harvard Educational Review*. Programmed instruction is popularly associated with the use of teaching machines, and the first such device was described by S. L. Pressey in 1926. A teaching machine is any device employed for the purpose of presenting a self-instructional program to a student. It may consist of a punchboard, or it may be an elaborate electronic device capable of presenting both visual and auditory material. It may be a textbook in which control of the sequence is achieved through the physical arrangement of the material on the printed page.

Techniques.—Several techniques of programming have been developed. The first of these is the linear, or straight-line, program. The logic for the development of this type of program evolved from studies of the differentiation of behaviour in laboratory animals. (For background information on such studies see BEHAVIOURISM; CONDITIONING; FEELING, PSYCHOLOGY OF; *Effects of Rewards and Punishments on Behaviour*; LEARNING: *Modes of Acquisition*; PSYCHOLOGY, EXPERIMENTAL.) In linear programming what a student should learn from a program, that is, a terminal behavioural repertory, is set up as the goal. Actions that successively approach the goal, the desired terminal behaviour, are reinforced, or rewarded, as soon as they occur. Responses that

do not lead toward the terminal repertory go unreinforced. The result is a shaping of the desired behaviour through differential extinction resulting from the nonreinforcement of undesired behaviour. Specifically, an item of information is given the student, he is required to answer a question or complete a statement and he is then provided with the correct answer for comparison with his own. He then proceeds to the next frame where the process is repeated. The subject is presented one step at a time, building from the simple to the complex. All students work through the same sequence, and a low rate of error is desired to ensure adequate reinforcement of appropriate responses. Initially, stress was placed upon the importance of moving in small steps by which the student might progress from the known to the unknown. It has been recognized, however, that students with various preparations and abilities can progress by different-sized steps.

It is important to note that in the case of programmed learning the primary responsibility for success of an educational technique is placed upon the technique itself rather than upon the student. In constructing a program co-operation is required among a programmer, a subject-matter expert and, most importantly, the students for whom the program is designed. A properly constructed program is tested out on the students themselves and their responses determine refinements in the order of presentation and other elements of its design. If what the students should learn has been specified clearly and the program adequately revised in response to the needs of individual students, then it will be an effective teaching instrument. The decisions the programmer must make in constructing a program as to the course of the program are influenced by the adequacy of different paths in eliciting or stimulating desired responses, that is, in controlling the student's behaviour. What may appear to be a logical organization of a subject matter may not necessarily be an effective organization from which to teach. For this reason it is said that the sequence developed within a program has psychological rather than logical unity or direction.

A second technique of programming, developed by Norman Crowder, is called branching, or intrinsic, programming. The branching program was initially developed in conjunction with the use of an electronic training device in training military personnel. The branching program emerged in its final form when Crowder introduced the innovation of explaining to the student why a particular choice he made was either right or wrong. The branching program presents the student with a piece of information, provides him with alternative answers and, on the basis of his decision, instructs him to advance to another frame. At the subsequent frame he is informed whether his choice was correct and, if not, is told why his choice was incorrect. The student then is either returned to the original frame or routed through a subprogram designed to remedy the deficiency indicated by his choice of a wrong alternative. When he selects the correct alternative, he moves to the next frame in the program. This process is repeated at each step throughout the program. A student may be exposed to differing amounts of material depending upon the errors he makes.

Although the linear and the branching formats do not exhaust all possible techniques of programming they have historic primacy, and the major controversies in the field have centred about the various features of one or both of these types of programming. A number of programs incorporate both linear and branching features. Typically, the linear program employs a constructed response: the student is required to write an answer to a question or to complete a statement for a particular frame. Since it is practically impossible to construct a branching program wherein all possible alternatives are anticipated, the branching program requires a multiple choice or "recognition response."

The relative effectiveness of the two response modes may be questioned but even more general questions may be raised. In teaching mechanical skills, for example, what is the effectiveness of any verbal response as contrasted with behaviour closer to the actual tasks to be performed? Bearing in mind that learning is considered to be a change in behaviour, the nature of the behaviour to be evoked is the final criterion in determining the instrument

to be employed for the purpose of conditioning that behaviour. In programs based primarily upon verbal behaviour the question of the most effective mode of presentation has led to the development of the so-called programmed textbook.

Applications.—Proponents have pointed out that programmed instruction releases teachers from many routine tasks so that they may devote more time to creative work in the classroom. From a single program in 1954 the field has seen the development of programs covering such academic subjects as grammar, foreign languages, mathematics, music, science and social studies. Programs have been written and used for levels of instruction ranging from primary through graduate school. The industrial and military uses of programs equal if they do not exceed academic uses. Interest in programmed instruction has developed in Canada, the U.S.S.R., Japan, Great Britain, France, Czechoslovakia and the Philippines. The possible application of these techniques to improving education in underdeveloped countries is immediately obvious and several agencies have concerned themselves with exploring the development of programmed instruction for use in underdeveloped nations.

Some educators have regarded programmed instruction as a supplement to traditional teaching methods. On the other hand, several authorities in the field have maintained that it is not merely a new instructional medium to be incorporated into an existing system of education but a discontinuity, a break with older philosophies of teaching, and the inclusion of programmed instruction in a conventional curriculum is a contradiction. As they see it, the techniques of programming implicitly contain a philosophy and technology of behavioural control that when pursued to a logical conclusion must result in a complete re-examination of educational philosophy and administration, including grading systems and curriculum organization.

PROGRAM MUSIC, the name given to instrumental music that carries with it some extramusical meaning, i.e., some "program" of literary idea, scenic description, personal drama, or national legend. It is contrasted with so-called absolute or abstract music, in which the artistic interest is supposed to be confined to tonal relationships, purely musical arguments, and abstract constructions in sound. Descriptive music is by contrast often regarded as less pure and, by implication, less good. Yet most of the great composers have been unable to resist the pleasure of depicting in music the sort of experiences that graphic artists put into genre painting, portraits, and conversation pieces. William Byrd wrote *The Battell*, a work in 15 sections for virginal; J. S. Bach the *Capriccio on the Departure of a Beloved Brother*; Beethoven *Wellingtons Sieg* and the *Pastoral Symphony*. These (except the symphony) are admittedly not among their composers' best works but they show that the thing can be done: external ideas, natural scenery, solid objects, even a railway engine (Honegger's *Pacific 231*) will go into music and there is really nothing reprehensible in a composer's putting them into music if he can.

Composers of instrumental music explored the possibilities of incorporating an external program at an early period. The *Fitzwilliam Virginal Book* (early 17th century) contains pieces about the weather, hunting, and battle. A little less than a century later—when the term "sonata" meant no more than something played, in antithesis to "cantata," which was something sung, and before what is now called "sonata form" was established by C. P. E. Bach—Johann Kuhnau, J. S. Bach's predecessor at Leipzig, wrote (among other keyboard sonatas) six "Biblical Sonatas" in which he indulges in many curious realistic effects in the representation of Saul and David, the healing of Hezekiah, and David and Goliath. In the last named, the flight of the slingstone which brought the giant to earth with a thud is a quick upward scale. This sort of realism can be not only naïve but also ridiculous: some of the formulas and clichés used to accompany silent films in the early days of the cinema were of the same order as Victorian descrip-

tions of battles, camels in the desert, and similar absurdities for drawing-room pianists. But with the development of the orchestra the range of experience expressible in music was enormously expanded—although certain specific references in the music could not be immediately identified without verbal clues being given. Controversy about the validity of program music developed into a first-class issue of musical aesthetics in the second half of the 19th century, when the "new music" of Liszt and Wagner was put into the scales against the classicism of Brahms, who never even went so far down the romantic road as to give descriptive names or fancy titles, as Schumann did, to his piano pieces. By the middle of the 20th century the issue was still alive, since Stravinsky went as far as to deny that music needed any expressive powers at all: it was just music. Though there was a truce of live-and-let-live during the 20th century—a truce of exhaustion perhaps—some new arguments were made available, namely symbolism from Freudian psychology and semantics from philosophy, with which to continue the debate.

The Place of Imagery in Music.—Like most other subjects program music can be discussed historically for the facts and critically for the values. Either approach has to deal with one vital fact of the musical imagination: composers have always set words to music, i.e., have gained some sort of conceptual content in music, whose thought is nonconceptual—have illustrated the meaning of the words by the flux and motions of music. They have even gone in for word painting, as in Thomas Weelkes' madrigal "As Vesta was from Latmos' hill descending," where the personages go up and down hill in rising and falling scale passages, two by two in two-part harmony and three by three in three-part harmony, leaving their goddess all alone in a brief soprano solo. Half the business of the accompaniment to a song is to evoke the mood of the poem by suggestion; the other half is to provide the harmonic context and support. Such suggestion operates through images: images of pitch to suggest height, depth, and position, and acuity, stress, or slackness of tension; images of tone-colour to suggest qualities of touch like warmth or hollowness; images of rhythm to suggest any kind of temporal phenomenon, spatial movement, gesture, duration, reiteration, repose, agitation, speed, and so on. These images constitute a language of music that was analyzed with a wealth of illustration in Deryck Cooke's *The Language of Music* (1959). Being images they are the material with which the musical imagination works. Musical imagery of all sorts, amassed by the composer from hearing music already in existence, is employed indifferently in vocal, symphonic, and program music.

Besides these true images, which are capable of taking on further symbolical meanings, there are some sounds in nature which can be imitated in music. Bird song is an obvious example, though it is more recalcitrant to musical treatment beyond the simple stage of the cuckoo-call than one would expect. Olivier Messiaen (b. 1908) is the only composer who made a sustained effort to integrate bird calls into serious composition. The cuckoo of course had a long run: L. C. Daquin's harpsichord piece "Le Coucou," Beethoven's *Pastoral Symphony*, and Delius' tone poem *On Hearing the First Cuckoo in Spring* immediately come to mind. Songs about the nightingale usually stylize the bird's performance. More like onomatopoeia are storms, of which opera can provide instances from Rossini's *Il barbiere di Siviglia* to Sir William Walton's *Troilus and Cressida*. Fire in Wagner's hands is presented not only with the crackle and swish of flames but with their visible edges perceptible by means of this mysterious process of the imagination which can convert visual imagery into audible imagery. Water is ubiquitous in music: fresh in Schubert, salt in Debussy—but the sea has many moods: boisterous in the overture to Wagner's *Der fliegende Holländer* (*The Flying Dutchman*); calm and lapping the shore with a phrase in the shape of a wave in Mendelssohn's *Hebrides* overture; or keen in scent, sound, and sight (seagulls, ozone, and shingle) in the first of the interludes in Britten's *Peter Grimes*, where the sea is an arpeggio of superimposed triads, and the dry land a chord of A major. But this is far beyond onomatopoeia, which, however, includes many made sounds like ships' sirens, steel anvils, church bells, striking clocks, and the rumble of railway trains—all of which can be ac-

commodated in small quantities in, though they invariably stick out of, musical compositions for dramatic or descriptive purposes.

The Problem of Form.—The powers of music to evoke situations in life, as well as to express human feelings, have been recognized by composers from the beginning: after all, imitation is instinctive. Thus vocal music has always used the descriptive devices of musical technique for every kind of expression. Though vocal music is excluded from the definition of program music, its relevance to the aesthetic issue cannot be ignored in quite the airy way that led the combatants in the 19th-century controversy to declare that music presented two separate sets of phenomena and aroused two sorts of emotion. Music is surely one, not two. But without cleaving the art in two it is possible to recognize the difference between a symphony and a symphonic poem. This difference is fundamentally one of logic and form, or perhaps the logic of form.

The ground plan of a symphony is four movements. In Beethoven's Third in E \flat (the *Eroica*), for example, the first movement is in sonata form with its exposition of two groups of themes in different but related keys, its middle section a development of these thematic ideas, and a recapitulation rounded off by a coda. The slow (second) movement is, somewhat exceptionally, a funeral march; the third a scherzo (with trio); and the fourth movement a set of variations. This is a satisfactory scheme for presenting some sort of experience, in this case heroism, in its several aspects, but it is singularly inept for depicting the life history of Napoleon, to whom the symphony was originally dedicated, for the hero is buried in the second movement and is fuller of life than ever in the third. Symphonic order is thus not to be reconciled with chronological order. Furthermore, if in the first movement any indication of the events in Napoleon's career had been the composer's intention he would have found that recapitulation would have made redundant nonsense of what had already been narrated in full. Sonata form is thus not to be reconciled with traditional narrative or drama, which moves on and does not go back. Hence the incongruity of using symphonic movements for ballets with a program, however sketchy, of biographical, historical, or dramatic events. So, when Richard Strauss wants to portray Don Juan's erotic adventures, Don Quixote's chivalric adventures, or (in the *Domestic Symphony*) a day in his family life, he does not employ sonata form, but modifies freely more episodic forms such as the rondo and variation form, or writes in the form of a loose rhapsody held together only by key coherence and the recurrence of themes symbolizing, like Wagner's *Leitmotifs*, the persons and events of the story. He writes in fact a symphonic poem. Both the symphonic poem, in which the form is subservient to the subject matter, and the term itself were invented by Liszt, who was thus the cause of all the controversy.

Tchaikovsky's *Hamlet* is a true symphonic poem; however, the story is told in a kind of sonata form, and this is done by disavowing out the chronological element of Shakespeare's play. When Robert Helpmann composed a ballet to it he began with Hamlet's "Ode on a Bier and the motto "Our little lives are rounded with a sleep," which fits Tchaikovsky's scheme wonderfully well. For if at the moment of death his past life flitted past Hamlet's eyes made no difference in what order the gravedigger and Ophelia and the ghost occurred. They were episodes which could be presented in symphonic order with their relationships expounded by themes, rhythms, keys, and orchestration (the oboe for Ophelia, for instance). Once this problem of logical sequence is solved the composer can go ahead and make music out of anything in the world except specific statements such as that the angles at the base of an isosceles triangle are equal, or propositions about monetary theory or the gold standard. Strauss himself did it, saying, in a moment of bravado and in answer to a challenge, that he could set a knife and fork to music. If he did not do that exactly, he bathed his baby, he disturbed a flock of sheep, he hanged a rogue, he produced the smell of ethyl chloride at a death bed, he confounded his critics, and he made love—but then love does not count as program music since it is all-pervasive.

The Romantic and nationalistic movements greatly enlarged the range of subjects that composers desired to express.

was well to the fore with *Faust* (Liszt and Wagner), *Romeo and Juliet* (Berlioz and Tchaikovsky), *Falstaff* (Elgar). Then came legend with *The Water Sprite* (Dvorak), *Tamara* (Balakirev), *The Sorcerer's Apprentice* (Dukas), *Scheherazade* (Rimski-Korsakov), and *The Swan of Tuonela* (Sibelius). Geography added a whole gallery of picture postcards: *The Steppes of Central Asia* (Borodin), *Bohemia's Woods and Forests* (Smetana), *The Fountains of Rome* (Respighi), *Paris* (Deliuss), London (Elgar, under the name *Cockaigne*), *Nights in the Gardens of Spain* (Falla), *Sinfonia Antartica* (Vaughan Williams), and *El Salón México* (A. Copland). Even philosophy was tried by Strauss in *Also sprach Zarathustra* (after Nietzsche), and pictures by Rachmaninoff in *The Isle of the Dead* (after A. Böcklin) and Liszt in *Hunnenschlacht* ("The Battle of the Huns," after W. Kaulbach). The concert overture form provided a rather shorter medium for program pieces such as Walton's two overtures *Portsmouth Point* (after Rowlandson's picture) and *Scapino* (after the *commedia dell'arte*).

Aesthetic Considerations.—The earlier examples of program music started an aesthetic battle which led Eduard Hanslick, the Viennese critic, to formulate his case against the genre in his book *Vom Musikalisch-Schönen* (1854; Eng. trans., "The Beautiful in Music," 1891). Hanslick argued that the aim of music was not expression but beauty. The conveyance of feeling, which he could not deny in the face of the universal recognition of music's powers in that respect, was incidental and subsidiary to its main purpose. This view was similarly promulgated at the beginning of the 20th century in the field of pictorial art by Clive Bell and Roger Fry, among English critics, who spoke of "significant form" as the element that constituted the artistic excellence of a picture. Likeness, representation, and subject matter, they held, were not only irrelevant to a picture's merits but might be an impediment to its true appreciation. It is a view not easily applied to literature; and in architecture which is not much subject to pressures of content or subject matter, there is function to be accounted for. Although this ruthless emphasis on form, which even consented to the banishment of literature from the realm of art, should have been a warning that there was something wrong with this theory, it found wide acceptance by the best critical minds, and painters themselves developed abstract painting, which corresponds in essentials to Hanslick's ideal music. Later avant-garde musicians of the 20th century claimed that in music sound alone mattered, and how to manipulate it—a doctrine readily understood in an age dominated by technology.

In favour, however, of the traditional view that basically music is expressive and that in this respect there is no difference between any of the kinds of music—vocal, instrumental, abstract, or programmatic—semantics now came to the rescue. Freud accustomed everyone to the pervasiveness of symbolism in thought, action, and art. A symbol is something that stands for something else, but it has a richer, more concentrated content of meaning, and the human mind has an innate tendency to create and use symbols. The symbols might at first be mere signs, like red for danger or a whistle for a summons to attention, but they have a tendency to grow into systems, such as language. Music is like language in being a system of signs and symbols with enormous powers of conveying meaning—especially meaning about states of mind. From this penetrating and fertile idea a whole philosophy of art was constructed by Susanne Langer, the U.S. philosopher, which is crystallized in one of her statements: "Music is 'significant form,' and its significance is that of a symbol, a highly articulated, sensuous object, which by virtue of its dynamic structure can express the forms of vital experience which language is peculiarly unfit to convey. Feeling, life, motion and emotion constitute its import." (Susanne Langer, *Feeling and Form*, p. 32. Routledge & Kegan Paul Ltd. and Charles Scribner's Sons, 1953.)

This doctrine avoids the dichotomy of the pure and the programmatic, for even a symphony can have emotional import. We can allow the title *Eroica* to Beethoven's Third Symphony without blushing and, though we should avoid racking our brains to conjure up novelettish "interpretations" of sonatas, string quartets, and symphonies, we need not fear to read them as documents re-

lated to human life, as something more than Hanslick's *arabesques sonores*, more also than contrapuntal algebra. They are documents related to the vital ebb and flow of our consciousness. Strauss, who wrote no symphonies after his Opus 12, recognized no distinction between abstract and program music, but only between good music and bad. It was good if it meant something, bad if it was meaningless. Good music for him was what expressed most. Tchaikovsky and Sibelius recognized that generalized emotion, abstracts of emotional experience, Langer's "pattern of life itself as it is felt and directly known," can be dealt with in symphonies, but that specific feelings arising from specific circumstances are matter for symphonic poems.

The Program Symphony.—Between the symphony and the symphonic poem there is an intermediate stage, the program symphony, illustrated by the *Pastoral Symphony*. Before Beethoven, Haydn had in his humorous way infused an element of external reality in small doses into the *Farewell*, the *Surprise*, and the *Clock* symphonies. But Beethoven in the *Pastoral Symphony* went the whole way and indicated in words what he was depicting: cheerful impressions on arriving in the country, the brook, the peasants, the storm, the shepherds' hymn—though he appeared to have some qualms about it, for he added, quite untruly, that it was more an expression of feeling than painting. From the *Pastoral* stemmed a line of program symphonies, in which the form was musically self-sufficient but the content contained extramusical matter in varying degrees of density: very thick in Berlioz' *Symphonie fantastique*, which purports to depict episodes in the life of an artist, and minimal in Mendelssohn's *Scottish* and *Italian* symphonies. Mendelssohn's *Hebrides* (or *Fingal's Cave*) Overture is probably the most beautifully balanced of such combinations since there is Mendelssohn's own testimony that the programmatic and the thematic idea of it were conceived simultaneously on the spot, at the cave. In Tchaikovsky's Fourth and Fifth symphonies the notion of fate embodied in the motto theme is elaborated to the extent vouched for in Tchaikovsky's own explanation; in his Sixth Symphony the title *Pathétique* is used in a general sense as far as a program permeates the music, at any rate until the extraordinary slow finale which is a clear premonition of death. Similarly in Dvorak's *New World Symphony* there is no detailed program but an allusion to the Negro in the slow movement. Vaughan Williams' *London Symphony* has rather more specific programmatic content in that it incorporates actual sounds from the London scene and employs the unusual combination of nocturne and scherzo, which somehow conveys the animation of London at night. The Soviet composers load their symphonies with significance, or have them loaded for them by commentators: Shostakovich's Seventh (*Leningrad*) Symphony was composed with the events of the defense of that city in mind. But in general the program symphony has grown less programmatic as the symphonic form has grown more ambitious.

Summary.—Program music increased in extent and status within the art through the program symphonies and symphonic poems of the 19th century. At the outbreak of World War I the aesthetic debate as to the propriety of program music had been going on for more than half a century. The swing of the pendulum after each of the world wars was toward neoclassicism, absolute music, sound manipulation, and aural austerity, in reaction to the enormous enrichment of the repertoire, the extension of orchestral resources, and the subtlety of music's expressive power during the previous heyday of the symphonic poem. By the second half of the 20th century, as a reaction against the austerities of the neoclassical style, the various literary and pictorial forms of program music were once again in the ascendant. (F. S. H.)

PROGRESSIVE EDUCATION. Although the sources of progressive education go back to far before the 1850s, the movement sprang into prominence in both the United States and Europe simultaneously but independently at the end of the 19th century. This article traces its origins and European development and then describes its considerable effect on U.S. education and its decline as a separate educational movement.

Origins and European Development.—Modern progressive education has its ancestry in a complex of ideas and practices

which, from the 16th century onward, have been concerned with a reconsideration of the nature of individual man, of the societies in which he lives and of the relationship between them. At different times the emphasis has fallen upon one side of the relationship or upon the other; now on the need to free the individual from social pressures which limit his development, now on the need to provide the kind of social environment which will foster this development. Jean Jacques Rousseau's *Émile* and *Du Contrat social* (1762) are source books for students of progressive education. The roots of the movement, as has been pointed out by W. H. G. Armytage, can be traced back to the utopian tradition which derived from Thomas More and Francis Bacon in the 16th century and embodied the notion that man can, as it were, make a fresh start, i.e., redeem the loss of the fall, by founding a new society or by restructuring an existing one. The implications of this for education are seen in the work of Samuel Hartlib, John Dury and J. A. Comenius; in the communitarian approach of the Quakers to both religion and education; in the work of Robert Owen and in the practical application of Rousseau's ideas by J. B. Basedow, J. H. Pestalozzi, Philipp Emanuel von Fellenberg and Friedrich Froebel.

The link between social reform and education is implicit in the movement which led to the founding of Abbotsholme school for boys, Derbyshire, by Cecil Reddie in 1889. Reddie was a member of the Fellowship of the New Life, founded in 1882. The fellowship promoted the founding of experimental schools, and the utopian tradition is clear in their assertion: "All schools ought to be communities, miniature commonwealths or states, as they were in the Middle Ages."

A secession from Abbotsholme led to the foundation of Bedales at Petersfield, Hampshire (1893); this later became the first co-educational boarding school. Later progressive schools in England were St. Christopher, Letchworth, Hertfordshire, originally intended as one branch of a many-sided community life; Frensham Heights, Farnham, Surrey; King Alfred's, Hampstead; Maltby House school, Cambridge; Beacon Hill near Harting, Sussex (founded in 1927 by Bertrand and Dora Russell); Summerhill, in Suffolk, founded by A. S. Neill; and Dartington Hall, Totnes, Devon. Most of these schools are coeducational and stress with varying emphases the freeing of the child from adult pressures and the provision of a rich and varied community life.

Abbotsholme inspired the founding in Germany of the Deutsche Landserziehungsheime (1898) by Hermann Lietz and in France that of L'École des Roches by Edmond Demolins in 1899. In Italy, in 1894, the sisters Agazzi opened a home for preschool children which stressed training in sense perception and play activities in rural surroundings, and this later became the model for preschool education in Italy. In 1907 Maria Montessori began her Children's Houses in Rome, and devised the "didactic apparatus" to enable children to develop their capacities by self-education (see MONTESSORI SYSTEM).

Other pioneers of new methods in education were Ovide Decroly in Belgium, Adolphe Ferrière in Geneva, and Elizabeth Rotten in Germany. In 1921 about 150 pioneers from countries throughout Europe met at an international conference in Calais, France, organized by Mrs. Beatrice Ensor who, in 1920, had initiated the *New Era*, a magazine for the exchange of ideas and experience concerning the new education. At this conference the New Education fellowship was formed to link pioneers in different parts of the world. After 1921 the fellowship organized many international conferences; national sections promoted its interests in 11 European countries as well as in Australia, India, Egypt, Pakistan, New Zealand, South Africa and South America. Until 1955 it was linked with the Progressive Education association of the U.S. (called, from 1945 until its end in 1957, the American Education fellowship).

After 1900, the progressive ideas and practices developed in the United States, especially those of John Dewey, flowed back to join with the European progressive tradition. The effect of this was to strengthen the emphasis on social education and the relating of the individual's needs to the needs of a rapidly changing society.

The influence on schools within state systems of education was

seen in the development of "activity" and "centre of interest" methods in the education of young children, in the use of "projects" and "assignments" with older children, and in general in the greater emphasis on social and emotional education and the modification of the formal and the academic in both content and methods. After 1946 there was a sharpening of the criticism of progressive ideas and methods, with restatements of the traditional aims, and this in turn challenged the progressive movement to redefine its assumptions and objectives. (J. W. T.)

United States.—In the United States progressive education began during the latter decades of the 19th century as one aspect of that larger program of social reform known as the progressive movement. It was essentially a pluralistic phenomenon, comprehending a remarkable diversity of pedagogical protest and innovation. In the universities it emerged as part of a spirited revolt against formalism in philosophy, psychology and the social sciences. In the cities it was but one facet of a wider program of municipal clean-up and reform. Among farmers it became the crux of a moderate, liberal alternative to radical agrarianism. It was at the same time the "social education" demanded by urban settlement workers, the "schooling for country life" demanded by rural publicists, the vocational training demanded by businessmen's associations and labour unions alike, and the new techniques of instruction demanded by avant-garde pedagogues. It enlisted to its cause parents and teachers, starry-eyed crusaders and hard-headed politicians. And in less than two generations it transformed the character of the U.S. school.

The sources of progressive education lie in part in the stream of pedagogical reform in Europe from the 17th through the 19th century cited above. They lie also in the revolution wrought before the Civil War by Horace Mann and his confreres in convincing Americans of the necessity of universal education in a free society. The very success of this revolution, in bringing into primary and secondary schools a greater diversity of children than ever before, inevitably exerted a transforming influence on the character of the schools themselves. Finally, the sources of progressive education lie in the transformation of society itself under the pervasive influence of industrialism. The advancement of technical and productive processes and the growing complexity of urban life—compounded in the United States by large percentages of non-English-speaking immigrants—led to pressures for the schools to assume educational responsibilities formerly borne by family, shop and neighbourhood.

The first evidence of progressivism in U.S. education appeared as early as the 1870s. Francis W. Parker, later referred to by John Dewey as the father of progressive education, undertook to reform the Quincy, Mass., schools beginning in 1875. He vigorously attacked rote learning and introduced new pedagogical techniques designed to make school subjects more meaningful to children. His reforms attracted national—indeed world-wide—attention as "the Quincy system."

Following upon the revelations of the Russian system of technical instruction at the Philadelphia centennial exhibition of 1876, Pres. John D. Runkle of the Massachusetts Institute of Technology, Calvin Woodward of Washington university, and Col. R. T. Auchmuty, a New York businessman, sharply criticized the narrow intellectual emphases in the secondary school program, demanding a central place for industrial training and vocational education. Throughout the 1870s conventions of the National Grange and other farmer organizations passed resolutions deploring the lack of practical agricultural training in schools and colleges.

Protests like these multiplied during the following decade, and by the 1890s they had assumed all the earmarks of a full-fledged social movement. The themes of this movement were many and various, but they were one in their attack on the narrowness and formalism of traditional education. Businessmen's organizations, and later labour unions as well, contended that under the modern factory system apprenticeship had deteriorated into an exploitive rather than an educative relationship and that because of this, schools should have to assume the classical functions of apprenticeship. Settlement workers, sensitive to the pedagogical vacuums created by broken homes and working parents, and compellingly

aware of the education of the streets, vigorously urged instruction in hygiene, domestic science, manual arts and child care. Likewise, rural educators, deploring the flight from farm to city, argued for a new kind of rural school which would orient young people to the joys and possibilities of country life and equip them technically to realize these possibilities. Finally, university professors and educationists, basing their proposals on the new sciences of psychology, sociology and pedagogy, pressed for revamped school programs which would afford greater importance to scientific studies, tie learning more closely to doing, and educate "whole children"—that is, pay attention to physical and emotional growth as well as to intellectual development.

Outstanding Americans from many walks of life espoused ideas such as these during the quarter-century before World War I, among them Theodore Roosevelt, Jane Addams, Jacob Riis, William James, Charles W. Eliot, Henry Wallace, Walter Hines Page, and James Earl Russell. No one saw the movement whole, though, quite as well as John Dewey, for 50 years the commanding figure among theorists of progressive education. In a series of books, pamphlets and essays, beginning with *The School and Society* (1899) and culminating with *Democracy and Education* (1916), Dewey illuminated the close relationship between progressive education and the larger social transformation being wrought by science, democracy and industrialism. The curse of traditional education, Dewey argued, had been its aristocratic character and its isolation from life. The crux of progressive education was its universality and its closeness to life. Dewey urged that schools be made into "embryonic social communities," active with the occupations and permeated with the values of the surrounding society. "When the school introduces and trains each child of society into membership within such a little community," he wrote, "saturating him with the spirit of service, and providing him with the instruments of effective self-direction, we shall have the deepest and best guarantee of a larger society which is worthy, lovely, and harmonious." (John Dewey, *The School and Society*, p. 44, The University of Chicago Press, 1899.) (See also DEWEY, JOHN.)

Progressive education made considerable headway on an experimental basis after 1890. Joseph Mayer Rice found in an 1892 survey that the school systems of Indianapolis and La Porte, Ind., and of Minneapolis and St. Paul, Minn., having freed themselves from undesirable political control, had begun to put teaching on a "scientific basis," to "develop the child in all his faculties instead of simply crowding his mind with facts," to introduce new work in manual and creative arts, and to seek desirable correlation among the several subjects of study. In 1896 John Dewey and his wife founded the Laboratory school in Chicago specifically to test the validity of his pedagogical theories. In 1904 Junius L. Meriam established an experimental school at the University of Missouri, Columbia, and in 1907 Marietta Johnson opened her School of Organic Education at Fairhope, Ala. The following year, William Wirt, school superintendent of the newly created steel town of Gary, Ind., began the sweeping educational innovations which came to be called the "Work-Study-Play" plan. Widely publicized by the progressive press after 1914, the Gary plan represented the best-known effort to apply Dewey's precepts to the public schools of a burgeoning industrial community. Finally, vocational education of every sort advanced rapidly after 1900, and in 1917 congress passed the Smith-Hughes act providing federal aid for trade, agricultural, home economics and distributive instruction in public secondary schools.

The founding of the Progressive Education association in 1919 marks a significant divide in the history of the progressive education movement, since what had formerly been a loosely defined revolt against pedagogical formalism now gained a vigorous organizational voice. Under the initial leadership of Stanwood Cobb and Eugene Randolph Smith, the association quickly gained a notable place in U.S. education. Its membership climbed steadily, passing 5,000 in 1927 and reaching a peak of 10,500 in 1938. Its quarterly, *Progressive Education*, launched in 1924, quickly became a clearinghouse for educational experiments of every conceivable kind. During the 1930s, aided by well over \$1,000,000 in foundation money, the association sponsored a number of widely

publicized experiments, among them an eight-year study involving 30 secondary schools and over 200 colleges and designed to test the effects of introducing greater flexibility into high school curricula. The results, published in 1942, were taken as decisively in favour of the experimental programs.

Spurred on by the efforts and propaganda of the association, progressive education won ever greater acceptance in school systems across the nation. Success, though, brought ideological schism in its wake; and the quarter-century after 1919 was marked by sharpening conflict over just what progressive education was, and what it meant. One group of educators, epitomized by Marietta Johnson, combined the doctrines of liberty and self-expression into a highly individualistic pedagogy which held that schools in which children are encouraged freely to develop their uniquely creative potentialities are the best guarantee of a larger society devoted to human worth and excellence.

A second group, following the leadership of George S. Counts during the 1930s, sought to tie progressive education much more closely to specific programs of political reconstruction, contending that educators could lead in the building of a new social order. A third group, typified by Elsie Ripley Clapp, saw the crux of progressive education in school activities directed to the social and economic regeneration of local communities. A fourth group, exemplified by Eugene Randolph Smith, concentrated on reorganizing and enlivening the traditional school studies. And finally, there were those like William Heard Kilpatrick, Boyd H. Bode and Dewey himself who continued to regard progressive education as the pedagogical expression of the larger philosophy of experimentalism, with its emphasis on naturalism, scientific method and democratic social planning. Given this conflict over goals, the movement during the later 1930s was increasingly paralyzed by a factionalism which weakened not only its forward thrust but its resistance to outside criticisms as well.

From its earliest days progressive education had elicited sharp and sustained opposition from a variety of sources. Humanists and idealists had vigorously criticized its naturalistic orientation, its Rousseauian emphasis on freedom and interest, and its cavalier treatment of the classics and foreign languages. During the 1930s a group calling themselves the Essentialists had taken progressives sharply to task for failing to pay sufficient attention to the need for disciplined study of systematic knowledge. A number of Christian educators, Roman Catholic and Protestant as well, had accused progressives of materialism and a general denial of supernatural spiritual values; while elements of the patriotic press had been unremitting in their charges of radicalism and "un-Americanism." Criticisms such as these became more insistent after World War II, when progressive doctrines in general seemed eclipsed by a revival of conservatism in U.S. politics and social thought. Unable to meet the challenge, the Progressive Education association disbanded in 1955; and the journal *Progressive Education* ceased publication two years later. For all practical purposes, the movement died in 1957, but not without leaving an indelible impress on U.S. education. (L. A. C.)

PROGRESSIVE PARTY, U.S. Three times in the first half of the 20th century a political party with this name took part in U.S. presidential campaigns—in 1912, 1924, and 1948.

The Progressive Party of 1912 began as an insurgent outbreak among Republican members of Congress in 1910 against the speaker of the House of Representatives, Joseph G. Cannon. Opposition to the administration of Pres. William Howard Taft crystallized in 1911 when the National Progressive Republican League was organized by Sen. Robert M. La Follette of Wisconsin. Theodore Roosevelt soon placed himself at the head of that movement. Alleging unfair tactics on the part of the "Old Guard," his followers left the Republican national convention in Chicago, Ill. (June 1912), and Roosevelt was nominated for the presidency by a Progressive national convention, also held in Chicago, early in August. Roosevelt's Progressive Party was popularly known as the Bull Moose Party. With the Republican vote split between Taft and Roosevelt, Woodrow Wilson, the Democratic candidate, carried all but eight states. The electoral vote was 435 for Wilson, 88 for Roosevelt, and 8 for Taft. Of the popular vote, Wilson received 6,293,454, Roosevelt 4,119,538, and Taft 3,484,980. In 1916 harmony was restored in the Republican Party when Roosevelt declined a second Progressive nomination and supported the Republican ticket. During World War I partisanship was in abeyance, but upon its termination the old rift soon reappeared. The administration of Harding encountered dissatisfaction among farmers, as did the Coolidge administration.

In 1924 Wisconsin and other farm states held a conference for progressive political action and launched a new Progressive Party. Senator La Follette was nominated for president and Sen. Burton K. Wheeler of Montana, a Democrat, for vice-president. The party platform promised a "house cleaning" of executive departments, public control of natural resources, public ownership of railways, and tax reduction. Republican strategy in 1924 consisted largely in denouncing the alleged radicalism of the La Follette platform, while ignoring Democratic attacks. Coolidge won easily; La Follette won 4,822,856 votes but carried only Wisconsin with 13 electoral votes. La Follette's death in 1925 led to the dissolution of the party.

Unlike its predecessors, the Progressive Party founded by Henry A. Wallace in 1947–48 stressed foreign issues in its platform—principally abandonment of the Marshall Plan (*q.v.*) and the Truman Doctrine (see TRUMAN, HARRY S.). This party was formally organized in Philadelphia, Pa., July 22–25, 1948, naming Wallace as its candidate for president and Sen. Glen H. Taylor of Idaho as its vice-presidential candidate. On Aug. 6 the national convention of the Communist Party of the U.S. announced its support of the Wallace-Taylor ticket. In the presidential election of 1948, the party polled only 1,156,103 popular votes and won no electoral votes.

PROHIBITION, the legal prevention of the manufacture, sale, or transportation of alcoholic beverages. In the United States, nationwide Prohibition was adopted when the 18th Amendment to the Constitution was ratified in January 1919. It was repealed by the 21st Amendment, December 1933.

The adoption and repeal of Prohibition in the United States are best understood in the context of the larger movement of temperance and as part of American social reform. Prohibition and temperance developed, remained, and declined in relation to the general framework of public opinion and social conflict concerning drinking in American culture. While the word "temperance" suggests moderate usage, it became identified with abstinence during the second quarter of the 19th century. In the early development of the antialcohol movement in the United States, the objective was temperate use and not abstinence. While the objective of abstinence became dominant, the name "temperance" remained with organizations and came to be a general label for the antialcohol movement. (See further **TEMPERANCE**.) Prohibition is the form of the movement that seeks abstinence through legal prohibitions.

I. THE PRECURSORS OF NATIONAL PROHIBITION

Temperance Organization in the Early 1880s.—Organized efforts to limit the use of intoxicating beverages did not begin on a large scale in the United States until the 1820s. Under the leadership of Congregationalist and Presbyterian ministers the first national temperance association, the American Society for the Promotion of Temperance, was founded in 1826 in Massachusetts. During the 1830s and 1840s this and other temperance organizations, such as the Sons of Temperance, gained large numbers of adherents. Early support came largely from Eastern states, but nationwide organizations soon developed. The intensive religious revivalism of the 1820s and 1830s stimulated movements toward perfectionism in human beings, including humanitarian doctrines, abolition of slavery, and temperance. It was out of this wave of temperance concern that movements for state and local Prohibition began. The expression "teetotaling" came into being in this period because temperance supporters indicated their total beliefs by a "t" opposite their names on temperance rosters.

Drive for Legislation.—During the 1840s and 1850s temperance people and temperance leaders were linked to a number of movements of a religious and humanitarian nature. Sabbatarianism, home missionary movements, abolitionism, nativistic feeling, and temperance were frequently linked together, many persons adhering to all of them. It was in this period that the temperance movement appeared as an important political link to other strivings. The efforts to legislate abstinence drew support from other movements and issues concerned with religious goals, humanitarian reform, and nativist hostility. The relation between temperance and abolition discredited the movement below the Mason and Dixon's Line; although it had begun well in the South, the temperance movement met with slight appeal in Southern states after 1840.

In 1838 the Massachusetts legislature passed the "15 Gallon Law," the earliest temperance law. It prohibited the sale of ardent spirits in quantities less than 15 gallons, effectively limiting sales to those wealthy enough to make purchases in large quantities. Although repealed two years later, it established the precedent of seeking temperance through law. In 1846 the first state Prohibition law was passed in Maine under the leadership of Neal Dow, mayor of Portland and a prominent temperance advocate. The Maine law, strengthened in 1851, ushered in a wave of state Prohibition legislation before the Civil War. By the 1850s state Prohibition was in effect in 13 states (New England plus Michigan, Minnesota, Iowa, Indiana, Delaware, Nebraska, and New York), although by 1863 only Maine still retained its law.

Temperance Literature and Ritual.—The transition in the temperance movement before the Civil War was one in which the aristocratic leadership gave way to that of the common man. Congregationalist ministers were replaced by more evangelical and revivalistic supporters. Along with this trend went the development of a highly emotional and popular literature appealing to

sentiment and stressing the reform of the drunkard. The development of the Washingtonian movement during the 1840s was in line with this trend. It began in Washington, D.C., and aimed at converting drunkards to total abstinence. This movement was marked by the development of flamboyant oratory and secular leadership, often that of reformed drunkards. These techniques of emotional drama and oratory marked the temperance movement, and Prohibition, throughout its course.

The Post-Civil War Period.—In the decade after the Civil War two major temperance organizations emerged. In 1869 the National Prohibition Party was founded, pledged in the 1872 presidential election to achieve nationwide Prohibition. The platform of 1872, and many others afterward, contained a reformist program expressing many of the same goals as the Grange and, in later years, the Populist Party. In 1874 the Woman's Christian Temperance Union (WCTU) was founded. Under the leadership of Frances Willard (*q.v.*) it was the leading temperance organization of the 1880s and 1890s in the United States. It was also active in a number of other social reforms, including women's rights, the labour movement, and the americanization of immigrants.

Both these organizations may be said to have reflected two major sources of concern. One, manifested to a larger degree in the WCTU, was a concern for the problems brought about by the industrialization of American cities and the arrival of millions of immigrants. The growth of cities with large non-Protestant populations presented the middle-class urban American with a need to assimilate new groups into his culture. The immigration and industrialism of the late 19th century made an appeal to the reformer's sympathies for human perfectionism and threatened the dominance of middle-class Protestant values. In preaching to the working-class and non-Protestant immigrants of the cities, temperance advocates were attempting to provide a similar set of middle-class values and habits that would unite the urban population.

The second source of concern was largely rural. In the Prohibition Party one saw a much stronger representation of the kinds of fears that Midwestern farmers and small-town residents had of the growing power of urban populations. During the 1880s men such as John St. John, Populist governor of Kansas and presidential candidate of the Prohibition Party in 1884, were noted for their combined temperance and Populist support. Both concerns continued to be effective into the 19th century.

These developing activities culminated in the second wave of statewide Prohibition that swept the country between 1880 and 1890. While not as many states passed Prohibition legislation as had during the 1850s, it is still true that more states were actively involved and Prohibition laws appeared before more legislatures than had been true in the earlier wave. By 1890 six states (Maine, Kansas, North Dakota, South Dakota, New Hampshire, and Vermont) had Prohibition laws or constitutional amendments. By the end of the 19th century there were 15 states that had had experience with state Prohibition at some time in their history. Nevertheless, only five states (Maine, Kansas, North Dakota, New Hampshire, and Vermont) still had Prohibition by 1900. Yet in that year approximately 23% of all Americans lived in "dry" areas.

II. 20TH-CENTURY ROOTS OF NATIONAL PROHIBITION

The drive for national Prohibition emerged out of a renewed attack on the sale of liquor in many states after 1906. The 13 years before passage of the 18th Amendment was a period of intensive state and national agitation for Prohibition laws. The dry fight had the support of churches, small towns, Progressivist sentiment, and rural political power. It was led by a new and highly effective organization, the Anti-Saloon League.

Rural-Urban Conflict.—Several underlying forces were at work to support the vigorous drive in the individual states and later at the national level. One of these, and a major force throughout the campaign, was antipathy to the growth of cities. As the United States became a more urbanized society, the in-

dustrial culture and the impact of immigration made the rural-urban conflict increasingly important in American politics. That conflict had strong overtones of cultural differences. It was largely in the small towns and agricultural areas of the United States that temperance sentiment had its strongest support. The urban and the eastern industrial areas were the centres of greatest opposition.

Protestant and Nativist Sentiments.—A second major source of Prohibitionist strength lay in the Protestant middle-class segments of the American population, especially the more evangelical ones such as the members of Methodist and Baptist churches. Although there had been some Catholic support for temperance societies, in the main both temperance sentiment and Prohibitionist sentiment stemmed from Protestant sources. A distinctly antialien and anti-Catholic sentiment was evident in much temperance literature of this period.

Rural Power.—Especially in its rural segments the Midwest represented another major source of temperance support. Here again the complex of agriculture, Protestantism, and nativism worked together to develop the drive for Prohibition as an attack on the new industrial and alien cultures that had developed in the big cities of the United States. Urban areas contained many residents whose cultural roots in American middle-class values gave rise to an antipathy to drinking. Political support for Prohibition, however, was heavily-rural.

The political power of the rural areas dominated state legislatures. Without it, the enactment of state Prohibition laws and the adoption of the 18th Amendment would have been extremely difficult. In a number of cases, statewide Prohibition came about through state legislative action rather than through statewide referenda. The political power of the rural areas was even stronger in its legislative representation than its numerical majorities within the population.

The Saloon.—The saloon was itself a powerful argument for Prohibition. During the 1890s and early 1900s Americans drank in quantities and in circumstances that have not been equalled since. The liquor and beer industries showed an enormous ineptitude in failing to control the worst features of urban saloons. Many were centres of organized prostitution and political corruption. They became vivid symbols of the manifold evils of urban society and municipal government.

Economic Arguments.—An industrial society found excessive drinking to be a far greater hazard than it was in a simpler agricultural community. The economic argument for Prohibition was aimed at two groups—employers and employees. Industrial employers were concerned with preventing accidents and with increasing the stability, punctuality, and discipline of the workers. In the 1880s and 1890s the Knights of Labor, under Terence Powderly, was openly allied with temperance organizations and waged a campaign to diminish drinking by its members. The American Federation of Labor, however, did not continue this policy. Some industrialists supported Prohibition but many did not. While economic considerations played a role in developing a climate of concern about excessive drinking, they were overshadowed as explanatory factors by religious and cultural elements.

Progressivism and the Populist Movement.—The Progressive movement of the early 20th century, although an urban one, saw in the saloon and in drinking that it fostered sources of the municipal corruption and industrial chaos that the Progressives sought to eliminate. In fighting for Prohibition they saw themselves fighting the organized underworld, the foundation of corrupt politics, and the source of the workers' low standards of living.

Populist political sentiments, represented to some degree by William Jennings Bryan in the 1896 presidential election, were expressed in the antiurban quality of the Prohibition movement and in the attack on big business. In the liquor industry Populists saw an enemy, like the railroads and the banks, that put profits above human values.

In the 20th-century movement for Prohibition both the Progressive and Populist strands in American politics came into an alliance for human perfection. The nativist sentiments that bound both of them together contained also the efforts toward the reform of

the immigrant for whom they felt a missionary zeal. They tried to lead the newcomers to perfection through an assimilation of middle-class values.

The Anti-Saloon League.—The Anti-Saloon League, founded in 1895, assumed leadership of the Prohibitionist cause in the state drives of 1906 to 1913. The League adopted a new strategy for temperance organizations and politics. Breaking with the Prohibition Party and its tactics, the League did not put up its own candidates for election. Instead, it operated on the policy of rewarding its friends and punishing its enemies within the two major parties solely for their stand on temperance issues. As a consequence the "drys" assumed a considerable degree of power within both the Democratic and Republican parties, at state and national levels.

The tactics of the Anti-Saloon League were not only those of intensive political pressure on candidates. They generated an intense support through the public opinion of church members. Utilizing the pulpit to spread their message, the ministry as a source of local leadership, and the congregation as a base of financial support, the League became a classic example of the successful American political pressure group. In 1906 only three states (Iowa, Kansas, and Maine), still had Prohibition in force. Between 1906 and 1912 seven states passed Prohibition laws. By 1919, before the passage of the 18th Amendment, an additional 19 states passed restrictive legislation, and more than 50% of the U.S. population lived in dry areas. Most of these shifts into the dry column had occurred by 1917 before adoption of the Amendment seemed highly probable.

By 1913 national Prohibition began to seem at least possible. With passage of the Webb-Kenyon Act (March 1913) forbidding transportation of intoxicating beverages into dry states, the "drys" achieved their first national legislative victory. The liquor and beer industries sensed trouble and made efforts to control saloons, but it was too late. By January 1920 Prohibition was already in effect in 33 states covering 95% of the land area and 63% of the total population of the United States. During World War I a temporary wartime Prohibition Act was passed to save grain for use as food. In 1917 the Hobson resolution for submission of the Prohibition Amendment to the state received the necessary two-thirds vote in Congress; the Amendment was ratified on Jan. 16, 1919, and went into effect on Jan. 16, 1920. The text of the Amendment was as follows:

Section 1. After one year from the ratification of this article the manufacture, sale, or transportation of intoxicating liquors within, the importation thereof into, or the exportation thereof from the United States and all territory subject to the jurisdiction thereof for beverage purposes is hereby prohibited.

Section 2. The Congress and the several States shall have concurrent power to enforce this article by appropriate legislation.

Section 3. This article shall be inoperative unless it shall have been ratified as an amendment to the Constitution by the Legislatures of the several States, as provided in the Constitution, within seven years from the date of the submission hereof to the States by the Congress.

III. THE PROHIBITION ERA

The Enforcement of Prohibition.—It was one thing to have passed the 18th Amendment but quite another to gain compliance with it. Laws that operate against segments of the population with strong counterelements can seldom expect complete compliance. The Prohibition laws are often viewed as examples of the ways in which a determined population can defeat the intentions of the legislators, but care must be used in making such a judgment. The extent of the enforcement of Prohibition is a matter of considerable debate. What can be said with some certainty is that, especially in urban areas, it was far from universally obeyed, nor was it energetically enforced.

Under the National Prohibition Act, popularly known as the Volstead Act (after Congressman Andrew J. Volstead of Minnesota), the commissioner of internal revenue of the Treasury Department was given the power to detect and suppress violations. In addition, individual states passed further enabling and enforcing legislation. All the states enacted laws to help carry the Volstead Act into effect although Nevada's was later held unconstitutional. Such state laws were repealed in five cases (New York in

1923, Wisconsin, Montana and Nevada in 1929, and Illinois in 1931.)

The support of the federal government to the enforcement of the Prohibition acts varied considerably during the 1920s. New personnel and new methods of Prohibition organization were tried and found wanting. Federal and state legislators did not grant sufficient funds to make possible a large legal and police organization. The salaries of Prohibition agents compared unfavourably with those of other public employees, and the entire staff of the Bureau of Prohibition never exceeded 4,500 men. The first Prohibition commissioner, John F. Kramer, served for a year and a half and was replaced by Roy A. Haines. Under President Coolidge a new head, Gen. Lincoln C. Andrews, was appointed. Andrews resigned in March 1927 and the position was thereafter held for short periods of time by several different people. Only after 1927 were all the employees of the Bureau required to take the civil service examinations. In 1929 the Department of Justice was given the duty of enforcing the 18th Amendment.

Drinking and Bootlegging.—There is considerable debate about the extent of drinking during the period of Prohibition. There is general agreement, however, that illegal manufacture and sales of liquor went on in the United States on a large scale, especially after 1923. In general, Prohibition was enforced wherever the population was sympathetic to it. In the large cities, where sentiment was strongly opposed to Prohibition, enforcement was much weaker than in rural areas and small towns. However, increased price of liquor and beer meant that the working classes probably bore the restrictions of urban Prohibition to a far greater degree than the middle-class or upper-class segments of the population.

Prohibition brought into being a new kind of criminal—the bootlegger. The career of Al Capone was a dramatic instance of the development of bootlegging on a large scale. His annual earnings were estimated at \$60,000,000. The rise of the bootlegging gangs led to a succession of gang wars and murders. A notorious incident was the St. Valentine's Day Massacre in Chicago in 1929 when the Capone gang shot to death seven members of the rival "Bugs" Moran gang. Historians of the underworld, however, suggest that by the late 1920s bootlegging was on the verge of semi-monopoly control and that the end of gang wars was approaching.

The Conflict Over Prohibition.—During the 1920s the temperance movement changed radically. The alliance between Progressive and social gospel wings of American Protestantism with the more Populist and Fundamentalist groups was greatly weakened. The increased role and leadership of the Fundamentalist and nativist groups in the temperance movement tended to drive away the less hostile and urban forces, such as those of the Federal Council of Churches of Christ in America. The excessive zeal and political pressure of the Anti-Saloon League and of the Methodist Board of Temperance alienated a number of former supporters. Events came to a focus in 1928 with the nomination of the governor of New York Alfred E. Smith, as the Democratic candidate for the presidency. The Ku Klux Klan aggravated the differences within the Prohibition movement and led to a partial political identification of Prohibition supporters with rural conservatism. The defection of the urban Progressivist wing was a major element in undermining the power and acceptance of Prohibition in American public opinion.

Movement for Repeal.—The opponents of Prohibition began to organize from the moment the law came into effect. The very failure to gain full compliance with the law led to disillusionment among a number of its supporters and to energetic attacks from others. As a consequence, the political power of the so-called "wets" prevented fuller enforcement.

As time went on, some of the major supporters of Prohibition became disenchanted with it. One of the major defections was that of the industrial leader, Pierre Du Pont. From a staunch contributor to Prohibitionist causes, he became one of the major supporters of the Association Against the Prohibition Amendment (AAPA), which became active in 1926. The AAPA borrowed a leaf from the Anti-Saloon League and flooded American magazines and newspapers with literature attacking the virtues of Prohibition

and highlighting the development of the criminal action of the bootlegging industry. The development of the "speakeasy," an illegal saloon, dramatized that decline of morality in many parts of the United States which has been associated with the 1920s. Prohibition was attacked in the name of individual freedom, and drinking was referred to as "striking a blow for liberty." By the middle of the 1920s newspapers and magazines carried numerous articles describing the lack of enforcement of the 18th Amendment. Prohibition leaders such as Wayne Wheeler, Purley A. Baker, and Bishop James Cannon were increasingly criticized.

In the presidential election of 1924 the Prohibition Amendment had not come under intensive consideration; both parties had pledged themselves to its enforcement. In 1928, however, the Democratic candidate repudiated his party's "dry" platform. He opposed Prohibition, and the 18th Amendment became a powerful issue in that campaign. While Smith lost decisively, he carried urban areas of the United States that had never before voted for the Democratic Party. The urbanization of the United States and the increase in the number of persons of voting age in the cities gave promise of an overthrow of the rural power that had been dominant in American politics. While Herbert Hoover gave Prohibition enforcement his support, the turning tides of politics were evident.

Repeal of the 18th Amendment.—By 1929 the demand for some change in Prohibition legislation was considerable although the form and scope of such changes was under considerable debate and discussion. There were those who sought a better and stricter enforcement. There were those who sought a less sweeping indictment of all intoxicating beverages and permission for the sale and manufacture of beer. There were many, however, who sought the complete repeal of the Amendment and the return to the manufacture and sale of liquor, wine, and beer.

As he had promised during the campaign, President Hoover appointed a commission of 11 prominent citizens to make "a thorough inquiry into the problem of the enforcement of Prohibition under the provisions of the 18th Amendment of the Constitution and laws enacted in pursuance thereof, together with the enforcement of other laws." This commission, appointed on May 29, 1929, was headed by George W. Wickersham, former attorney general of the United States. The Wickersham Commission's final report was generally interpreted as critical of the 18th Amendment, although it did not favour repeal. Two of the commissioners favoured repeal; five wanted revision to provide for government monopoly of the liquor traffic; two favoured revision and a further trial of the 18th Amendment; and two supported the existing situation with minor alterations.

The polarization of the two parties in the 1928 election served to identify the Democratic Party as "wet" and the Republican Party as "dry." This was a break with the tactics of the Anti-Saloon League, which had avoided associating any one party with either side of the question. Analysis of votes on the Jones Act (1929) that increased penalties for first offenses against the Prohibition acts shows that the split between the North and the rest of the country on questions of Prohibition was more pronounced than ever. The consequent identification of wet and dry with specific political parties meant that the Democratic victory in the 1930 congressional elections was identified as one favouring the wet cause. In 1932 both parties adopted platforms calling for modification. The Democrats, however, adopted a platform calling for repeal, and the Democratic victory in 1932 was thus considered a mandate for the repeal of the 18th Amendment.

Forces for Repeal.—It is important to recognize the enormous significance of the depression of 1930-33, which affected Prohibition in two ways. First, it strengthened the economic argument for the return of the liquor and beer industries. While labour unions had been cool to the 18th Amendment, after 1930 they were vociferous in demanding repeal as a way of producing jobs in liquor and beer industries. Many businessmen saw in the abolition of the 18th Amendment a return to a source of tax revenue that might ease their own tax burdens. Even such stalwart contributors to the Prohibition cause as John D. Rockefeller, Jr. and S. S. Kresge deserted. A second, and perhaps even more significant

effect of depression on repeal, was the shift in attention in American political life to the problem of unemployment. The new urgency of economic issues made Prohibition a relatively minor matter. The polarization of political forces into rural-urban, Protestant versus Catholic, or immigrant versus alien was weakened by economic issues. These tended to make income levels and class differences far more important as political elements and to diminish those social antagonisms from which the Prohibition question drew its strength.

In February 1933 the Senate and House adopted a joint resolution proposing the 21st Amendment to the Constitution repealing the 18th. On Dec. 5, 1933, Utah became the 36th state to ratify the Amendment and repeal was achieved.

Post-Repeal Legislation.—After repeal a few states continued statewide Prohibition, but by 1966 all had abandoned it. The control of liquor and beer in the states in the 1960s varied widely from statewide provisions to systems of local option. In general, there was still a considerable degree of liquor and beer control or outright Prohibition in numerous parts of the country. Despite the passage of time, there was relatively little change in public support for, or opposition to, liquor control. In 1939, 18.3% of the American people lived in locally dry areas. By the 1960s this percentage had only declined very little despite the repeal of state Prohibition in Kansas and Oklahoma. In general, liquor control in the United States came to be determined more and more at local levels. Rural areas and small towns usually demonstrated a much more stringent attitude toward liquor and beer use than did the cities.

American Culture and the Antialcohol Drives.—The United States is relatively unique in the scope and intensity with which it has attempted to legislate against the use of alcoholic beverages. While Aztec society, ancient China, feudal Japan, the Polynesian Islands, Iceland, Finland, Norway, Sweden, Russia, Canada, and India have all attempted some system of Prohibition, only Finland and the United States have ever experimented with national Prohibition. (Finland adopted it in 1919 and repealed it in 1931.) India is the only other country that has attempted a system of Prohibition for any length of time on a fairly large scale.

In the complex of values which has characterized the American Protestant middle classes, self-mastery, industry, thrift, and moral conduct have been signs of the attainment of prized character traits. Self-denial has been viewed as a necessary step to the achievement of social and economic success. Drunkenness and indulgence are signs of unethical conduct because they are signs of a lack of personal control. This ascetic strain in American Protestantism has tended to make for a perfectionist bent in American religion and moral conduct which operates both as a self-oriented set of rules and a disposition to perfect the wayward, the weak, and the alien. The rural, native American Protestant of the 19th century respected temperance ideals. Sobriety was virtuous, and in a community dominated by middle-class Protestantism it was necessary to social acceptance and self-esteem. As American life began to change with the advent of urbanization and the influx of immigrants, these values were called into some doubt. Prohibition demonstrated for a while at least the dominance of that way which was reflected in the ideal of temperance and abstinence. As contemporary America became far more oriented toward values of consumption and toward a more leisurely life such values had less and less resonance in American culture.

Other Countries.—The countries of Northern Europe, especially Finland, Sweden, and the U.S.S.R., have shown a special concern for prevention of alcoholism through liquor control. The absence of ingredients for wine and beer production in these countries has led to frequent use of beverages with high percentages of alcohol. The Finnish experiment with prohibition of sales of spirits was an effort to induce a shift away from such spirits to greater beer consumption. It was unsuccessful and led to a situation of tensions similar to those in the United States. Sweden experimented with systems of rationing liquor use by the individual through a system of national monopolies, which minimized profits,

and a system of liquor ration books, which led chronic drunkards to lose their purchasing privileges. Over the years, however, Sweden moved to greater permissiveness toward drinkers. In these countries, including the U.S.S.R., alcoholism continued to be a great problem.

Amounts and kinds of drinking, as well as systems of control, vary considerably among cultures and societies. The French are heavy users of wines and have the highest alcoholism rate in Europe. The Italians are also heavy wine users but they have one of the lowest alcoholism rates. Neither country has experienced a strong temperance movement. In India, where abstinence is enjoined as a virtue among high-caste Hindus, a strong anti-alcohol movement succeeded in passing prohibitory legislation in many parts of India, especially western India. In 1965 Bombay reversed its legislation and repealed its prohibitions on liquor and beer sales.

Cultures differ both in their attitudes toward drinking and in their systems of control. Studies of American Jews and Italian-Americans have shown high acceptance of drinking as a social custom but a norm directing moderate use. Among the Japanese, drunkenness is accepted and the drunkard simply prevented from harming himself or others. Some societies have attempted to control the drinker, as under the Swedish system, while others, such as the United States, have aimed at the seller. There is little evidence that alcoholism is more or less of a problem under one than another system.

PROHIBITION PARTY (U.S.), a minor political party having as its primary objective the enactment of laws prohibiting the manufacture and sale of intoxicating liquors. Founded in Chicago, Ill., in 1869, the party reached its greatest national strength in the presidential election of 1892 when it obtained 271,000 out of a total of 12,000,000 votes cast. Its candidate that year was Gen. John Bidwell of California, and its platform included woman suffrage, currency reform, and other proposals in addition to prohibition. The party vote declined greatly while the 18th (prohibition) Amendment to the Constitution was in effect, 1919-33; it rose again slightly after the 21st Amendment (repeal of prohibition) was ratified. Although the party has offered presidential and vice-presidential candidates in each national election since its founding, its most effective work has been in local and county elections. The mass of prohibition sentiment has preferred to find expression through other organizations, especially the Anti-Saloon League and the Woman's Christian Temperance Union, rather than through the party. Advocates of prohibition resort to the political campaign primarily to keep the idea of prohibition before the public. Among American third parties, the Prohibition Party remains the oldest. See also PROHIBITION; TEMPERANCE (C. F. McL.)

PROJECTION, in geometry, is an operation performed upon points, lines, and planes by which a range of corresponding points or a surface of projection is formed. Let A, B, C, D , etc., represent points of a straight line l and A', B', C', D' , etc., points of another straight line l' in the same plane with l . If the straight lines AA', BB', CC', DD' , etc., are all perpendicular to the line l' , the set of points A', B', C', D' , etc., is said to be an orthogonal projection of the set, A, B, C, D , etc. (fig. 1). The correspondence between the two sets of points, by which A corresponds to A' , B to B' , etc., is called an orthogonal projection. In case the straight lines AA', BB' , etc., are all parallel, without being necessarily perpendicular to l' , we use the term parallel projection instead of orthogonal projection (fig. 2). In case the lines AA', BB', CC' , etc., all meet in a point O we speak similarly of central projection. In all three cases we say that the two sets of points A, B, C, D , etc., and A', B', C', D' , etc., are in perspective and that the points of one set are projected into the points of the other set. The point O is called the centre of perspectivity or the centre of projection of the two sets of points as indicated in the accompanying diagram (fig. 3).

FIG. 1.—ORTHOGONAL PROJECTION

FIG. 2.—PARALLEL PROJECTION

FIG. 3.—CENTRAL PROJECTION

These conceptions have been generalized in various ways. For example, let A, B, C, D , etc., be the points of any figure F in space and A', B', C', D' , etc., be corresponding points of a figure in a plane π . If the straight lines AA', BB', CC' , etc., are all parallel or all meet in a point O the figure in the plane π is called a projection of the other figure. If the lines AA', BB' , etc., are all perpendicular to the plane π , the figure in π is called an orthogonal projection of the other figure.

See also DESCRIPTIVE GEOMETRY; GEOMETRY: Projective Geometry; PERSPECTIVE; PROJECTIVE GEOMETRY. (O. V.)

PROJECTIVE GEOMETRY is a branch of pure mathematics that originated in the problems of perspective drawing and the making of optical instruments. These practical applications, however, are now studied under the names of descriptive geometry and optics (*qq.v.*); and the name projective geometry is given to a logical discipline that provides greater abstractness to ordinary geometry and an intimate link between geometry and algebra, this in turn providing the basic ideas for the more recently developed theory known as algebraic geometry (*q.v.*). In this article only a very general introduction to the subject can be attempted; for proofs see works in the *Bibliography*.

Perspective Projection.—The distinctive procedure of projective geometry is the representation or mapping of one line l or plane π onto another (l' or π') by perspective projection from any point O not lying in either (see *PROJECTION*). This is essentially what is done when a plane object is drawn or photographed from any viewpoint. The construction whereby the image of any point P of the object π (or l) is obtained as the intersection of π' (or l') with the line OP is not limited (as in drawing a picture) to any finite portion of π (or l).

From the elementary point of view, the object of projective geometry is the study of those properties of figures that are not altered by this mapping; i.e., properties that are the same for the "picture" as for the object, and are not altered by any number of repetitions of the mapping. If, for instance, a plane π is mapped by projection from O_1 onto a plane π_1 , this in turn from O_2 onto a plane π_2 , and so on, till a mapping on a plane π' is reached, this mapping of π onto π' is called a general projective mapping, and any property of a figure that is unaltered by the first projection will be the same in π' as in π . With certain exceptions, considered in the next paragraph, each point of π has an image point in π' , and each line of π is mapped onto a line of π' .

Points at Infinity.—It is familiar that in an ordinary perspective (*q.v.*) drawing of π on π' there are certain points (and one

line) in π' that correspond to nothing in π . That is, the images of a family of parallel lines in π are lines in π' all passing through one point, which is thus not the image of any point of π ; and all the points of π that thus arise from different parallel families in π lie in one line h' , the so-called horizon of the picture. Similarly, there is a horizon h in π , that has no image in π' ; but all the lines that pass through one point of h have images in π' that are parallel.

This causes confusion, awkward exceptions to otherwise very general theorems, and similar inconveniences. These difficulties are overcome by adding, to each plane, fictitious or ideal points to correspond with those of the other plane that have actually no images. It is agreed conventionally that every line contains just one ideal point, or point postulated as being at infinity, which can be approached (though of course not reached) by traveling very far along the line in either direction; that all lines parallel to one another contain the same point at infinity; that all points at infinity in one plane form a line called the line at infinity; and that all planes parallel to one another contain the same line at infinity. Thus the horizon h' is the image of the line at infinity in π , and similarly the image of the line h is the line at infinity in π' . Finally, all the points and lines at infinity in space form a single plane at infinity.

(It is not suggested, of course, that these ideal points, lines, and planes have any physical existence; but then, neither have any of the pure concepts of geometry, e.g., the point that has position without magnitude; the line that has length without breadth.)

This concept of the ideal not only gives every point and line in π an image in π' , and makes every point and line in π' the image of one in π , but also removes troublesome exceptions from many general propositions; e.g., that every two coplanar lines intersect in a point, every two planes intersect in a line, and so on. These, with similar propositions (e.g., that every two points are joined by a line and every two intersecting lines by a plane), are clearly basic to projective geometry, and when the subject is treated axiomatically such are the axioms assumed; they are known as the projective axioms, or axioms of incidence.

Projective Theorems.—Theorems dealing solely with inter-

FIG. 1.—DESARGUES' THEOREM

sections of lines and collinearity of points include the following, which may be cited as playing an important role in any logical development of projective geometry.

Desargues' Theorem.—If $ABC, A'B'C'$ are two triangles, in one plane, such that AA', BB', CC' meet in a point, the intersections of BC with $B'C'$, of CA with $C'A'$ and of AB with $A'B'$ are all in one line (see fig. 1).

Pappus' (Pascal's) Theorem.—If A, B, C are in one line, and A', B', C' in another line in the same plane, the intersections of BC' with $B'C$, of CA' with $C'A$, and of AB' with $A'B$ are all in one line (see fig. 2). For more details see *GEOMETRY: Projective Geometry*.

Duality.—In the plane there is a kind of symmetry between points and lines called duality. In the statement of any proposition or the specification of any figure, if the words point and

line, lies in and passes through, intersect in and are joined by, etc., be interchanged throughout, a new proposition or figure is obtained, called the dual of the first. For instance, the axioms, "any two points are joined by a unique line," and "any two lines intersect in a unique point" are dual to each other. It is possible to frame the axioms for a logical treatment of projective geometry in pairs dual to each other; and then if any theorem is true, so is its dual, for the translation indicated above need only be made all through the proof.

FIG. 2.—PAPPUS' (PASCAL'S) THEOREM

Dual to the line, thought of as consisting of all the points in it, is the figure of all lines through a point; say, L . This is called a pencil of lines, and can be denoted by (L) . Dual to the mapping of one line l on another l' by projection from a point O , is the mapping of a pencil (L) on another (L') , so that lines a, b, c, \dots in the one intersect their images a', b', c', \dots in the other in points all lying in a fixed line o (see fig. 3).

FIG. 3.—MAPPING OF A PENCIL OF LINES

In solid geometry there is the same sort of duality, not between points and lines, but between points and planes, lines being dual to lines. Thus the axioms "any two points are joined by a line" and "any two planes intersect in a line" are dual to each other, as are "any two lines in one plane intersect in a point" and "any two lines through one point are joined by a plane." The dual of a plane, regarded as consisting of all the points and lines in it, is called a star, and consists of all the planes and lines through a point. Geometry in a star is closely similar to that in a plane, lines and planes playing the roles of points and lines respectively. A star can be projectively mapped on another star, or on a plane; for instance the star can be mapped on any plane π not belonging to it, by taking as the image of any line or plane of the star its point or line of intersection with π . The dual of a line of points consists of all the planes through one line, and is called a pencil of planes.

Projectively Generated Loc.—Geometry, of course, contains many figures besides those consisting only of points and lines (and planes, in solid geometry); for example, the circle. If a plane π is mapped projectively on a plane π' , the image of a circle is generally not a circle, but a curve called a conic section (*q.v.*), or more briefly a conic; and the image of any conic is likewise a conic. The conic can be defined in projective terms as follows:

If two pencils of lines in one plane be taken, say (O) and (O') , and the one be mapped projectively on the other, in general, *i.e.*, unless the line OO' in (O) has itself as image in (O') , the aggregate of intersections of a line with its image consists precisely of the points of a conic; this is the definition of a conic in projective geometry.

Many other curves and surfaces can be defined similarly. For instance, if two lines l, m are skew (*i.e.*, are not in one plane and do not intersect), and if l is mapped projectively on m , the lines joining each point of l to its image generate a surface (*q.v.*) called a ruled quadric; *i.e.*, the points of the surface are all the points of all the lines. This family of lines is called a regulus; it can also be defined as consisting of all lines that intersect not only l and m but a third line n , skew to both l and m . The important ruled quadric theorem states that any line intersecting three lines of a regulus intersects all of them. Such lines form a second regulus, generating the same surface, of which l, m, n are members.

Again, if a pencil of planes be mapped projectively on two others, the points of intersection of a plane with its two images are in general the points of a curve, called a twisted cubic; and if a star be mapped projectively on two others, the points of intersection of a plane with its two images are the points of what is called a cubic surface.

HOMOGENEOUS COORDINATES

Coordinates (*see* ANALYTIC GEOMETRY) are useful in projective geometry, allowing problems to be formulated as equations and solved by algebraic methods. However, in an ordinary Cartesian coordinate system in the plane, the coordinates (x, y) of a point at infinity are in general both infinite, but have a definite ratio to each other, x/y , depending on the direction of the parallel lines through the point. Calculations with infinite quantities of this kind are confusing, and it is found convenient to represent each point, not by the two numbers (x, y) but by three numbers (x_0, x_1, x_2) such that $x = x_1/x_0$, $y = x_2/x_0$. Obviously, if k is any number except zero, (kx_0, kx_1, kx_2) denote the same point as (x_0, x_1, x_2) . If now $x_0 = 0$, then $x = x_1/x_0$ and $y = x_2/x_0$ are infinite, but have the definite ratio $x/y = x_1/x_2$; the numbers $(0, x_1, x_2)$ thus denote a point

at infinity, obviating calculation with infinite coordinates.

Such a method of representing points is called a homogeneous coordinate system, because any equation in (x, y) is equivalent to a homogeneous equation (*i.e.*, one in which all the terms are of the same degree) in (x_0, x_1, x_2) ; for instance, any line has an equation of the form $a_1x + a_2y + a_0 = 0$, which on substituting x_1/x_0 , x_2/x_0 for x, y and multiplying by x_0 becomes $a_0x_0 + a_1x_1 + a_2x_2 = 0$. (The line at infinity, incidentally, has also an equation of this kind, namely $x_0 = 0$.)

However, as well as the homogeneous coordinate system (x_0, x_1, x_2) , any other can equally be used, say (x'_0, x'_1, x'_2) , derived from it by a linear transformation:

$$(A) \quad \begin{aligned} x'_0 &= a_{00}x_0 + a_{01}x_1 + a_{02}x_2 \\ x'_1 &= a_{10}x_0 + a_{11}x_1 + a_{12}x_2 \\ x'_2 &= a_{20}x_0 + a_{21}x_1 + a_{22}x_2 \end{aligned}$$

where the nine coefficients a_{00} , etc., are sufficiently general to let these equations be solved, so as to express (x_0, x_1, x_2) in the similar form

$$(B) \quad \begin{aligned} x_0 &= b_{00}x'_0 + b_{01}x'_1 + b_{02}x'_2 \\ x_1 &= b_{10}x'_0 + b_{11}x'_1 + b_{12}x'_2 \\ x_2 &= b_{20}x'_0 + b_{21}x'_1 + b_{22}x'_2 \end{aligned}$$

Such a transformation leaves the equation of a line still linear, and indeed does not alter the degree of any algebraic equation in the coordinates.

The transformation (A) can, however, be thought of in another way. When it is a change of coordinate system, (x_0, x_1, x_2) and (x'_0, x'_1, x'_2) are the coordinates of the same point in two different homogeneous coordinate systems; but they can also be taken as the coordinates of two different points, P, P' , in the same system. The equations then define a mapping of the plane onto itself; equations (A) define for every point P a unique image P' and equations (B) show that every point P' is the image of a unique point P . This is in fact the general expression for a projective mapping of the plane onto itself.

In the same way, if (x, y, z) are Cartesian coordinates of a point in space, this can be denoted instead by the homogeneous coordinates (x_0, x_1, x_2, x_3) , where $x = x_1/x_0$, $y = x_2/x_0$, $z = x_3/x_0$. Every plane has an equation $a_1x + a_2y + a_3z + a_0 = 0$ in the Cartesian coordinates, and hence $a_0x_0 + a_1x_1 + a_2x_2 + a_3x_3 = 0$ in the homogeneous coordinates; in particular, $x_0 = 0$ is the equation of the plane at infinity. A transformation like (A), but consisting, of course, of four equations each with four terms on the right, can in the same way as equations (A) be used either to define a new homogeneous coordinate system or to specify a mapping of space onto itself, in which the image of any point (x_0, x_1, x_2, x_3) is the point (x'_0, x'_1, x'_2, x'_3) . This proceeding maps every plane projectively onto a plane, and every line projectively onto a line, and is called a projective mapping of space.

Duality finds a very simple expression in terms of coordinates. In plane geometry, if the equation of a line l is $a_0x_0 + a_1x_1 + a_2x_2 = 0$, then (a_0, a_1, a_2) are called the homogeneous coordinates of l , and the equation is regarded as the condition for the line (a_0, a_1, a_2) to pass through the point (x_0, x_1, x_2) . What is called a dual mapping of the plane onto itself can be defined by taking as the image of every point P the line with coordinates that are the same as those of P ; the images of the points in a line l will then be the lines through the point L , with coordinates that are the same as those of l . This dual mapping can be defined in purely geometrical terms, but the definition in terms of coordinates is simpler.

Duality in space can be similarly treated, the homogeneous coordinates of a plane being the coefficients (a_0, a_1, a_2, a_3) in its equation $a_0x_0 + a_1x_1 + a_2x_2 + a_3x_3 = 0$.

Geometry of One Dimension.—Similarly a homogeneous coordinate system (x_0, x_1) can be used in a line, the position of a point in the line being determined by the ratio x_0/x_1 , and a linear transformation

$$(C) \quad x_0 = ax_0 + bx_1, \quad x'_1 = cx_0 + dx_1$$

giving either a transformation of coordinates or a projective mapping of the line on itself. As, however, there is only one point at

infinity to consider, there is no serious inconvenience in using the single coordinate $z = x_0/x_1$, in terms of which equations (C) become

$$(D) \quad z' = \frac{az + b}{cz + d}, \quad z = \frac{dz' - b}{-cz' + a}$$

this is known as a homographic transformation.

If $z = \alpha, z = \beta, z = \gamma, z = \delta$ are the coordinates of four points A, B, C, D of the line, the expression

$$(E) \quad \frac{(\alpha - \gamma)(\beta - \delta)}{(\alpha - \delta)(\beta - \gamma)}$$

is found to be unaltered by the transformation (D), and thus represents a property of the four points that is independent of the coordinate system and that is unaltered by a projective mapping. This number is called the cross ratio of the four points. If z is a Cartesian coordinate, the differences $\alpha - \gamma$, etc., in expression (E) are proportional to the segments AC , etc.; thus if in any projective mapping of the line on another line or on itself the images of A, B, C, D are A', B', C', D' ,

$$(F) \quad \frac{A'C' \cdot B'D'}{A'D' \cdot B'C'} = \frac{AC \cdot BD}{AD \cdot BC}$$

although, of course, neither the length of a segment AC nor the ratio of two segments such as AC/AD will in general be equal to $A'C'$ nor to $A'C'/A'D'$ respectively.

The Fundamental Theorem.—If A, B, C are any three points of one line, and A', B', C' are any three points of either the same or another line, a projective mapping may be constructed in which the images of A, B, C are A', B', C' respectively. This can be done in a great variety of ways; but the fundamental theorem of projective geometry states that the actual mapping will always be the same; i.e., however the construction is made, the image of any fourth point D will be the unique point D' satisfying equation (F). This is closely related to the fact that a transformation of coordinates can be made such that any three chosen points shall have assigned values for their coordinates; in particular, if the values $z = \infty, z = 0, z = 1$ are assigned to A, B, C , the value of z at any other point D will be equal to the cross ratio of the values given for A, B, C, D .

Harmonic Pairs.—Especially important is the case in which the cross ratio has the value -1 ; i.e., when C and D divide the segment AB internally and externally in the same ratio. In this case C, D are said to separate A, B harmonically. If A, B, C are given in a line, the point D can be constructed, such that C, D separate A, B harmonically by a purely projective construction (fig. 4). Lines are drawn through A, B, C to form a triangle PQR (QR passing through A , RP through B , and PQ through C); then if S is the intersection of AP with BQ , that of RS with ABC is the required point D .

All these ideas and results can be transferred to the points of a conic or of a twisted cubic curve, or to the lines of a pencil or a regulus, or any other aggregate that can be mapped projectively on a line. Such a mapping is simply taken and each member of the aggregate is given the same coordinate as its image point; four members have the same cross ratio as their image points, two pairs separate each other harmonically if their image points do so, and so forth.

COMPLEX GEOMETRY

There are many geometrical problems which, when attacked algebraically by means of coordinates, require the solution of a quadratic equation; for instance, in the most elementary analytic geometry, that of finding the intersections of a line with a circle, or with any conic. A more important problem is that of finding the fixed points (i.e., those that are their own images) in any

projective mapping of a line onto itself. If $z' = z$ in equations (D), it follows that

$$(G) \quad cz^2 + (d - a)z - b = 0$$

so that if and only if z satisfies this equation, the point with coordinate z will be its own image in the mapping (D).

As long as operation is confined to real numbers, a quadratic equation may have two solutions, or only one, or none at all. Correspondingly, in the plane of a circle there are lines that meet it in two points (the chords), in one point (the tangents), and not at all (those completely outside the circle). In algebra, however, great simplification is obtained by enlarging the concept of number to include what are called complex numbers (q.v.), of the form $a + ib$, where a and b are real numbers and i is an imaginary quantity with its square equal to -1 . Every quadratic equation with coefficients that are complex numbers has two solutions that are themselves complex numbers; these may, however, be equal. In particular, if the coefficients are real, either both solutions are real or neither is.

A similar simplification is obtained in geometry by the conventional introduction of complex points, taking in fact any set of three (or, for solid geometry, four) complex numbers to be the homogeneous coordinates of a point. It can then be said, for instance, that in a plane every line meets every conic in two points (which may coincide, the line being then a tangent of the conic). If from the elementary point of view, and as seen in a figure, there are no common points, then the points are imaginary and the equations make it possible to write down definite imaginary values for their coordinates. In the same way, every projective mapping of a line on itself has two fixed points which may coincide.

This conventional extension of complex geometry is logically similar to the addition of points at infinity, and has similar advantages in making it possible to state results in a more general form without the need to enumerate many alternative cases of each theorem.

Metrical Properties.—In plane geometry, a bodily rotation about a fixed centre, whereby each line through the centre is turned through the same angle, is a projective mapping of this pencil of lines on itself. The fixed lines of this are imaginary, and have always the same two directions; i.e., those given in any Cartesian coordinate system by the equations $y = ix, y = -ix$. Lines having either of these directions are called isotropic; they have the paradoxical properties that every isotropic line is perpendicular to itself; and that the distance between any two points joined by an isotropic line is zero.

The points at infinity in these two directions are often called the circular points at infinity, since every circle in the plane cuts the line at infinity in these same two points. In particular, a circle of radius zero (which in Euclidean geometry consists only of its centre) in complex geometry consists of the two isotropic lines through its centre.

The set of all projective mappings of a plane on itself form a group (see GROUPS); projective geometry consists of the study of those properties of figures that are unchanged by all the operations in this group. If, however, within this group is considered the smaller group (or subgroup) consisting of only those mappings in which the circular points at infinity are their own or each others' images, then every figure is the same shape as its image; though they may differ in size or scale, as well as in orientation and position. Euclidean geometry, in which the basic measurable quantities are the size of an angle and the ratio of two lengths, thus turns out to be the study of properties of figures that are unchanged by all operations of this smaller group, called the similarity group. All the ordinary properties of a figure can be expressed as its projective relations to the circular points, and to the line at infinity that joins them. In particular the angle between two lines can be expressed in terms of their cross ratio with the two isotropic lines through their intersection, and they are perpendicular if they separate the isotropic lines harmonically.

Intermediate between the similarity group and the full projective group is what is called the affine group, consisting of all mappings in which the line at infinity is its own image. Properties

FIG. 4.—PROJECTIVE CONSTRUCTION OF HARMONIC-PAIR DIVISION WITH CROSS RATIO OF -1 (see TEXT)

unchanged by these include parallelism and the ratio of parallel segments, but not angles or other length ratios.

If the imaginary circular points be replaced by two real points, the similarity group becomes that of the so-called Lorentz transformations in relativity theory (see RELATIVITY); and if instead the mappings in which a particular conic is its own image be considered, non-Euclidean geometry is obtained (see GEOMETRY, NON-EUCLIDEAN).

ABSTRACT GEOMETRIES

At this stage, points have little resemblance to the intuitive idea of a point in a drawable figure. They are nothing but sets of numbers (coordinates), and the geometrical theorems about them are only a peculiar way of stating algebraic results about homogeneous equations, especially of the first degree. But algebraically there is no more interest in equations in three variables (plane geometry) or four (solid geometry) than in those in any number. It is therefore agreed to call a set of $n + 1$ numbers (x_0, x_1, \dots, x_n) a point of n -dimensional space, always with the proviso that if k is not zero, (x_0, x_1, \dots, x_n) and $(kx_0, kx_1, \dots, kx_n)$ are the same point. The sets that satisfy r independent linear homogeneous equations are those of an $(n - r)$ -dimensional space lying in the whole space. All the propositions about joining spaces and intersections can be summed up in the following intersection theorem: If two spaces of p and q dimensions are joined by an r -dimensional space and intersect in an s -dimensional space, then $r + s = p + q$; if they have no intersection the formula is satisfied by the conventional value $s = -1$.

The idea of projective geometry can be extended by choosing coordinates from a wide variety of algebraic systems. Any set of symbols that can be added, subtracted, multiplied, and divided in the usual way is called a field (see FIELDS); for instance, the real numbers are a field and the complex numbers are another field; and we have seen the difference between the geometries obtained by using coordinates from these two fields. Many other kinds of field are possible, however. Some consist of only a finite number of "numbers"; the simplest consists only of 0 and 1, with the relation $1 + 1 = 0$; this being what ordinary arithmetic reduces to if all even numbers are called 0 and all odd numbers are called 1. When coordinates are chosen from this field plane a geometry is obtained consisting of only seven points and seven lines (three points in each line and three lines through each point). Similarly it is possible to construct a solid geometry of 15 points, 35 lines, and 15 planes. (See GEOMETRIES, FINITE.)

Algebra also offers systems of symbols, such as quaternions (*q.v.*), that can be added, subtracted, multiplied, and divided nearly in the usual way, but in which a product ab is not necessarily equal to ba . These are called skew fields. Using such a system for coordinates, a geometry can be constructed in which the usual joining and intersecting relations are valid, but in which certain theorems of ordinary geometry, notably that of Pappus, and what have been called the fundamental and ruled quadric theorems, are no longer true.

The topic can be approached from a different point of view by saying that any (finite or infinite) aggregate of things that fall into classes satisfying relations of a certain kind can be regarded as the points of a projective geometry. For instance, if a number of men belong to a number of clubs, and if every two men belong to just one club, and every two of the clubs have just one common member, then the men can be called points, and the clubs can be called lines, to give a projective plane geometry. Seven men A, B, C, D, E, F, G and seven clubs with three members each, say (ABD) , (BCE) , (CDF) , (DEG) , (EFA) , (FGB) , (GAC) , form a geometry that is structurally indistinguishable from that constructed from the field consisting of 0, 1 only; in fact, coordinates belonging to this field can be attached to each man so that each club is defined by a linear equation.

Similarly, if there are objects called points, grouped into classes of various sizes called lines, planes, etc., then if these classes satisfy certain relations (of which the chief is what has been called the intersection theorem), this gives a geometry whose number of dimensions depends on the number of different sizes of classes.

Much modern research has been devoted to the classification of all kinds of abstractly possible geometries in this sense, and to the discovery of what groups of theorems are equivalent; *i.e.*, such that in any geometry where one holds, the others hold also. For instance, Pappus' theorem and the ruled quadric and fundamental theorems are equivalent in this sense.

There are three known main categories of projective geometry:

1. Those in which both Desargues' and the Pappus group of theorems hold. These can be of any number of dimensions and can consist of either a finite or an infinite number of points. This class includes the ordinary real and complex geometries. Every geometry of this kind is structurally equivalent to that constructed with some definite field; and its properties completely determine, and are completely determined by, those of the field.

2. Those in which Desargues' theorem holds, but not Pappus' theorem nor those that go with it. These likewise can be of any number of dimensions, and can be similarly constructed from a skew field. They always contain an infinity of points. All geometries of three or more dimensions belong to one of these two classes.

3. However, there can also be plane geometries in which not even Desargues' theorem holds. A good many examples, both finite and infinite, have been constructed; but any general classification of these has proved one of the most intractable problems in modern geometry.

History.—The conception of points at infinity goes back to the 17th-century work of G. Desargues (*q.v.*) and many of the ideas of projective geometry can be traced in antiquity; but projective geometry may be said to appear as a distinct study in 1822 in the work of J. V. Poncelet (*q.v.*). The clear separation of projective from metrical properties dates from the publication of the *Geometrie der Lage* of K. G. Ch. von Staudt in 1847. Most geometers of the 19th century made some contributions to the study, notably L. N. M. Carnot, C. J. Brianchon, M. Chasles, A. F. Möbius, G. Monge, J. Steiner, J. Plücker, L. Cremona, H. J. S. Smith; as well as J. D. Gergonne and H. Wiener. Working out of the relations of metrical properties to the subgroups of the projective group, and of relations between a geometry and its coordinate field or skew field was largely due to F. Klein (see KLEIN, (CHRISTIAN) FELIX). The axioms and logical structure of the subject have been studied by many mathematicians, notably M. Pieri and O. Veblen. The possibility of non-Desarguan plane geometry was first demonstrated by H. F. Moulton, and this branch was studied in the 20th century notably by Ruth Moufang and M. Hall.

PROJECTOR, an optical system used to form the image of an illuminated object upon a surface. The essential elements of a projection system include the object to be imaged, a source of light to illuminate the object, an optical system that forms the image, and some surface (usually a screen) to receive the image so that it can be viewed by the observer. All of the elements in the system may assume various forms depending on the nature of the object to be viewed and the purpose for which it is to be projected. For information on motion-picture projectors, see MOTION PICTURES: History: Photography.

Slide Projector.—One of the most familiar types of projectors is that used for projecting colour slides taken by the amateur photographer. In this the light source is an electric lamp with a concentrated filament. A condensing lens concentrates the light into the projection lens, as shown in fig. 1. The lens, in turn,

FIG. 1.—SLIDE PROJECTOR

images the slide onto the screen. The small size of the slides makes it possible to use a compact optical system, and since the light can be concentrated through the slide, a great deal of the light may be gathered from the lamp filament and a bright image produced. Common types of amateur slide projectors employ a specially designed 500-w. lamp, a projection lens with a large aperture, and an efficient condenser. Such a projector will provide a bright image for an audience of more than 100 persons. Larger slide projectors for commercial use accommodate slides $3\frac{1}{4} \times 4$ in.; theatrical slide projectors for very large auditoriums may use carbon-arc lamps with very high light output and slides as large as 5×7 in.

Overhead Projector.—Slides up to 10×10 in. are used with the overhead projector, which has become a popular training aid in both schools and industry. In this projector (fig. 2), the slide

FIG. 2.—OVERHEAD PROJECTOR

rests on a horizontal surface, with the light source beneath and the lens above. A mirror mounted with the lens projects the image to a screen behind the instructor so that he faces the class while projecting the slide. Using a plain piece of plastic and a dark crayon he can also write or sketch as he lectures. The image is projected as it is produced.

Opaque Projector.—Opaque projectors are used to project nontransparent objects (for example, a solid object, a newspaper clipping, or the like). The illumination must be supplied to the object from the side facing the lens. Instead of the light being concentrated through the lens by a condenser, only the light scattered from the object reaches the lens and then the screen. For this reason, even with very high wattage lamps and very fast lenses, it is not possible to produce very bright screen images.

Auxiliary Equipment.—The screen is an important adjunct to a projector. A white matte surface reflects a bright image that can be viewed from any point within a very wide angle. Other

types of screens concentrate the light over a narrower angle, thereby providing a brighter image within the angle. Some projection systems employ a translucent screen on which the image is projected from one side, while the audience views it from the other. Typical home screens are either "beaded," consisting of a layer of fine glass beads embedded in a white plastic surface, or "lenticular," having a coating of transparent plastic over a white or aluminum surface. The plastic or lenticular screens are embossed with fine ribs in the form of cylindrical lenses that can be designed to provide nearly any desired distribution of light to the audience.

Microscopes may be equipped with high-intensity light sources and small projection screens so that small objects may be projected at very high magnification. To reduce undesirable heating of biological specimens, the illuminating system must be equipped with filters to remove as much as possible of the infrared light.

Microprojectors equipped with fixed rear-projection screens and object holders that can be moved under the control of very precise measuring screws are widely used in industry for inspecting complex mechanical parts. (M. G. T.)

PROKHOROV, ALEKSANDR MIKHAYLOVICH (1916—), Soviet physicist awarded the 1964 Nobel Prize for Physics, jointly with N. G. Basov and C. H. Townes, for fundamental research in quantum electronics (masers and lasers), was born at Atherton, Queensland, Austr., on July 11, 1916, his father being a Russian revolutionary émigré. Taken to the U.S.S.R. after the Revolution of 1917, Prokhorov graduated from Leningrad University in 1939. After army service in World War II (1941 to 1944, when he was wounded and demobilized), he obtained his doctorate (1951) at the P. N. Lebedev Institute of Physics, Moscow, one of the main research institutes of the Academy of Sciences. In 1954 he became head of the institute's Oscillations Laboratory. He is a professor at the Moscow State University. Having worked on masers and lasers since 1950, Prokhorov was awarded a Lenin Prize in 1959, together with Basov, for their joint suggestion of the maser principle in 1953. (D. T. H.)

PROKOFIEV, SERGEI SERGEEVICH (1891–1953), one of 20th-century Russia's most gifted composers, who wrote instrumental music, operas, and ballets. He was born at Sontsovka, in the Ekaterinoslav Government, on April 23 (new style; 11, old style), 1891, began to compose at the age of six, and wrote an opera at nine. After private lessons from Reinhold Glière he entered the St. Petersburg Conservatory, where he studied composition with A. K. Liadov, orchestration with Rimsky-Korsakov, and the piano with A. N. Essipova (1904–14), and won the Rubinstein Prize in 1914 with a performance of his own First Piano Concerto. The concerto had already been performed publicly in 1912, and the Second in 1913; while still at the conservatory Prokofiev was already the young hero of the Russian modernists. In the three years before the Revolution he did much to justify their hopes, producing the First Violin Concerto, the *Classical Symphony*, an opera *The Gambler*, the *Scythian Suite* for orchestra, the Third and Fourth Piano sonatas, and a number of songs and short piano pieces. In the summer of 1918 he left Russia and traveled by way of Japan and Honolulu to the U.S. There he wrote an opera, *The Love for Three Oranges*, for the Chicago Opera Company, which produced it in 1921; and began another, *The Flaming Angel* (the score of which was left in Paris and never performed during the composer's life). In the meantime Sergei Diaghilev had invited him to Europe for the Paris and London productions of his ballet *The Buffoon* (1921). He made his home first at Ettal in Bavaria, then (autumn, 1923) in Paris, working on the *Angel*, a fifth piano sonata, the Third Piano Concerto, and the Second Symphony. In Paris he wrote two more ballets for Diaghilev, *Le Pas d'acier* (produced 1927) and *L'Enfant prodigue* (produced 1929); and one, *Sur le Borysthène* (produced 1932) for the Paris Opéra. The Third and Fourth symphonies were based respectively on material from *The Flaming Angel* and *L'Enfant prodigue*.

In 1927 Prokofiev visited Russia: a number of his works were performed at that time in various cities. He paid another visit in 1929, and at the end of 1932 he returned permanently to his native

land. In the music written after his return Prokofiev emphasized the naïve and lyrical aspects of his art and modified the asperities of his harmony, but there is evidence that, in doing so, he was following the curve of his natural development, not merely bowing to the official demand for "socialist realism." The period before World War II was prolific: he wrote the opera *Simeon Kotko* (1940); another ballet, *Romeo and Juliet* (produced 1938); *Zolyushka* (*Cinderella*) (1945); the Second Violin Concerto (1935), based on film music; the witty orchestral suite *Lieutenant Kizhe* (1934), also drawn from film music; and a quantity of lesser works such as *Peter and the Wolf* (1936), a children's introduction to the instruments of the orchestra. The chief works of the World War II years were the Tolstoyan opera *War and Peace* (first version finished in 1942), the Fifth Symphony (1944), three piano sonatas, and a quantity of chamber music. During the artistically reactionary period after World War II Prokofiev suffered some official rebuffs: his Sixth Symphony (1947) was only half approved, the third violin sonata (unaccompanied, Opus 115) remained unperformed, and the opera *Story of a Real Man* (1948) was suppressed on the eve of production. Bowing to criticism, he produced during his last years "democratically acceptable" works such as the ballet *Tale of the Stone Flower* (produced 1954), the "oratorio" *On Guard for Peace* (1950), the Seventh Symphony (1952), and a revised version of *War and Peace* (1952). He died suddenly in Moscow on March 5, 1953.

Prokofiev's early reputation as an *enfant terrible* was unjust. He was from first to last a creator of vigorous, clean-cut "pure music." Being of his age, he was not a romantic: his marked lyrical gift was never placed at the service of subjective expression. But he commanded a genuine epic power that showed itself first in the *Scythian Suite* and very markedly in the film score *Alexander Nevsky* and other works of his Soviet period. At the other end of the scale he had wit and simple charm. He showed marked skill in accepting the requirements of "socialist realism" without, except in a very few instances, compromising his artistic integrity.

PROKOP, the name of two generals of the Hussites (q.v.) in Bohemia.

1. **PROKOP HOLY** (that is, Prokop the Bald or the Shaven) is said to have been the nephew of a Prague merchant. Though he was an Utraquist priest (i.e., administering Holy Communion under the forms of both bread and wine), he became the foremost leader of the Hussite forces in the later period of the Hussite wars, commanding them at their victories at Usti nad Labem (1426) and at Domazlice (1431) as well as during their frequent incursions into Hungary and Germany. The Bohemian invasion of Saxony (1429) led to Prokop's concluding the Treaty of Kulmbach with Frederick I of Brandenburg (Feb. 6, 1430). Having been one of the leaders of the fruitless Hussite embassy to the Council of Basel in 1433, Prokop on the resumption of hostilities besieged the Romanists in Plzen till indiscipline in his own camp forced him to withdraw to Prague.

When the Bohemian nobles, both Romanists and Utraquists, formed a league against the Taborites, a struggle began in Prague itself. Prokop tried in vain to defend the more democratic "new town" of Prague against the nobles and the citizens of the old town; then, having called the other Prokop (see below) to his aid, he retreated eastward with him. At Lipany, between Kourim and Kolin, their forces, mainly Taborites, were defeated by the nobles, and Prokop Holy was killed in the battle (May 30, 1434).

2. **PROKOP THE LESSER** was likewise a priest and a military leader. When Jan Zizka, commander of the moderate Taborites or "Orphans," died (1424), Prokop succeeded him in command of his army. Subsequently he took part in Prokop Holy's campaigns in Germany (see above). He continued the siege of Plzen when Prokop Holy had to abandon it. Finally he was recalled to Prokop Holy's side and was sharing the command of the Taborite Army with him when they were both killed at Lipany. (R. R. Bs.)

PROKOPOVICH, FEOFAN (1681–1736), an important ecclesiastical and political figure in Russia under Peter the Great and an active partner in Peter's work of reform, was born in Kiev on June 18 (new style; 8, old style), 1681, the son of a merchant. Originally named Eleazar Prokopovich, he was at first a member of the Uniate branch of the Catholic Church and was educated in Poland and at the Jesuit College in Rome. On his return to Russia in 1702 he became Orthodox, took the monastic name of Feofan and embarked on a career at the theological academy in Kiev. His eulogistic references to Peter, as well as his energy and learning, won the attention of the tsar, who in 1716 called him to St. Petersburg and made him his principal collaborator in the church reforms. It was Prokopovich who drafted the *Dukhovnyy reglament* ("Spiritual Regulation") of 1721: this abolished the patriarchate and instituted, after the model of Lutheran ecclesiastical administration, the Holy Synod, of which Prokopovich became the first vice-president. The new institution was aimed at making the church an administrative department of the state. Prokopovich went farther than any other Russian prelate in his readiness to support Peter's policy of secularization and westernization and was his most trusted adviser against the opposition of the main body of the church. He also militated against the prevailing Roman Catholic and scholastic tendencies in Russian Orthodox theology.

Prokopovich's other famous work is a political treatise, *Pravda voli monarshei* ("The Truth of the Monarch's Will" 1722). This, as well as his sermons and orations, is Protestant and secular in tone. It is inspired with a cult of enlightened despotism and with a hero-worship of the great tsar which was even more pagan than Protestant. Most of his works are composed in Latin, which he knew better than Russian. He also wrote poems and plays, designed mainly to propagate Peter's drastic measures for transforming Russian life. Archbishop of Novgorod from 1724, he died at Karpov on Sept. 19 (N.S.; 8, O.S.), 1736.

Prokopovich was an unattractive, high-handed character. Yet he had wide cultural interests and contributed greatly to the growth of learning in Russia. He helped to bring into being and to organize the Russian Academy of Sciences. He was a powerful speaker, and his funeral oration on Peter the Great remained for a century the most famous piece of Russian solemn oratory.

See I. A. Chistovich, *Feofan Prokopovich i ego vremya* (1868); N. P. Morozov, *Feofan Prokopovich kak pisatel* (1880). (E. Lr.)

PROKOPYEVSK, a town in Kemerovo oblast of the Russian Soviet Federated Socialist Republic, U.S.S.R., lies on the Aba River, a tributary of the Tom, 27 km. (17 mi.) NW of Novokuznetsk (formerly Stalinsk), on the railway to Novosibirsk. Pop. (1959) 281,958. A small village of 18th-century origin, it expanded rapidly in the 1920s to become the largest coal-mining centre of the Kuznetsk Basin (Kuzbass) industrial area. Some of the coal seams are up to 130 ft. thick. There is a large coal enriching plant. Coal miners' lamps are made at Prokopyevsk and there is a coal research institute. Other important industries are flour milling and the manufacture of machinery for mills and grain elevators. (R. A. F.)

PROLETARIAT. In ancient Rome the proletariat constituted the body of poor, landless freemen. It included artisans and small tradesmen who had been gradually impoverished by the extension of slavery. The proletariat (literally meaning "producers of offspring") was the lowest rank among Roman citizens; the first recognition of its status was traditionally ascribed to Servius Tullius. Its power resided exclusively in the rights its members enjoyed as Roman citizens. In some periods of Roman history it played an important role, not as an independent force but as a mass following, in the political struggles between the Roman patricians and the wealthy plebeians. Since it had little opportunity for productive work, which was performed in the main by slaves, its existence was largely parasitic on the Roman economy. On occasions it was quieted by doles of bread from the state and diverted by spectacles—"bread and circuses."

Marxian Socialist Theory.—The proletariat, in the restricted usage adopted by Karl Marx (q.v.), designates the class of wage workers engaged in industrial production whose chief source of income is derived from the sale of their labour power. As an

economic category it is distinguished in Marxian literature from the poor, the working classes and the *Lumpenproletariat*. Because of its subordinate position in a capitalist society and the effects of periodic depressions on wages and employment, the proletariat is described by Marxians as usually living in poverty. But it is not therefore identified with the poor, for some members of the proletariat, the highly skilled or labour aristocracy, are recognized as not poor, and some members of the entrepreneurial class as not wealthy. Despite synonymous use in agitational literature, the term proletariat is distinguished from the working class as a generic term. The former refers to those engaged in industrial production, the latter to all who must work for their living and receive wages or salary, including agricultural labourers, white-collar workers and hired help occupied in the distribution services. The *Lumpenproletariat* consists of marginal and unemployable workers of debased or irregular habits and also includes paupers, beggars and criminals.

The proletariat in this sense appeared comparatively late on the historical scene. Its existence is essentially bound up, according to Marxian analysis, with the development of modern capitalism. Many causes have been assigned for the emergence of the proletariat, the chief of which is the expropriation of the peasants from their individual holdings by the statutory enclosure of commons land, forced sales and bankruptcies, thus compelling them to drift to the cities where they could find a market for their power to work. The proletariat was therefore considered as an urban phenomenon whose size was vastly extended by the Industrial Revolution. Among the contributory factors of the process of proletarianization have been cited the breakup of the medieval guilds, the dispersion of the monasteries, the liberation of the serfs and large increases in the population relative to the possibilities of employment in traditional vocations. The incidence of these factors on the rise of the proletariat varied from country to country.

Capitalist Class as Creator and Enemy of Proletariat.—According to the Marxian analysis, the existence of the proletariat as a definite class presupposes the existence of the capitalist class. Where the capitalist class disappears or becomes subordinate in the control of production to other social groups that abrogate the free market, there is no longer a proletariat. This conclusion, together with the prediction that in the course of its evolution capitalist society necessarily becomes polarized into two classes, was questioned in the light of 20th-century developments in Germany, the U.S.S.R. and the United States. The assumption that in time the proletariat would constitute the overwhelming majority of the population was also challenged on the ground that increasing mechanization and rationalization of production led to a relative decline in the number of unskilled, manual workers and an increase in the numbers of those engaged in managerial functions and distribution services.

More significant in Marxian theory than its meaning as a strictly economic category is the social-psychological conception of the proletariat. Slowly educated by their hardships and their struggles for better conditions and wages, the workers are believed to become conscious of the objective antagonisms that divide them as a class from their employers. The first stage in their awareness is usually marked by the organization of trade unions within the existing framework of society. The second is their acceptance of doctrines which teach either that they cannot permanently improve their human existence in a commodity-producing society because unemployment, crisis and war are endemic to its operation, or that a more just and efficient organization of social relations is possible which would increase their material welfare and remove invidious social distinctions. The third stage is reached in the development of political parties which take on the designation of labour or socialist parties whose ultimate program is directed not to the improvement of the individual lot of the worker or to facilitating social mobility from class to class but to the reconstruction of the whole society which, in abolishing all traditional economic classes, would abolish the proletariat as a class.

Further, by setting up a common faith and objects of ideal allegiance, Marxians seek to unify the diverse ethnic, religious and

national differences among the proletariat and to reinforce the sense of solidarity which is presumably born out of consciousness of common material interests. In respect to this function of proletarian ideology, it should be observed that it enjoyed some limited success in overriding ethnic and religious differences among the members of the proletariat, but failed almost completely in transcending consciousness of national differences. In times of national conflict, the proletariat behaved no differently from the *bourgeoisie* of their respective countries.

Marxians seek organizational support for their ideology primarily, but not exclusively, among industrial workers for two reasons. The first is the assumption that whereas the economic grievances of all other working groups, such as the farmers, intellectuals and lower middle classes, can be removed without fundamental social change, the position of the industrial worker is so tied up with the exigencies of capitalist production that he cannot be liberated except by transformation of capitalism itself. The second is the expectation that, in the event of a struggle for power, the industrial workers will be most strategically situated in determining the issue—an expectation also called in question by the development of modern industrial and military technology.

Communist Party the Self-Designated "Vanguard of the Proletarian."—The appeals of proletarian ideologies nevertheless have been addressed to the community at large, to all men of "insight" and "good will," couched in moral terms which try to invoke the ideals of justice, humanity and human freedom. Many elements in the population are won to adherence to proletarian causes whose social antecedents are by no means proletarian. It has been widely observed that many outstanding political leaders of working-class parties in all countries have been drawn from other classes. And since most inspirers of proletarian ideologies have rarely been members of the working class, it has been inferred that the working class, left to itself, is not likely to develop beyond the level of trade unionism. The universalism implicit in the premises of proletarian ideologies led their carriers to proclaim that they represented the best understood interests not only of one class in the community but of the masses of people. In this way the voice of moral prophecy acts to give force and persuasive effect to the analysis of historical destiny. The result, sometimes concealed, sometimes acknowledged, is a broadening of the meaning of proletariat from a term designating a narrow economic class to a term that loosely encompasses all who support the ideology of the class, and ultimately to the masses who are presumed to enjoy its future benefits.

The various ambiguities in the meaning of the term proletariat come to a head in the phrase "the dictatorship of the proletariat." As Marx used it, it denotes the political rule of the proletariat, through representative organs, during a transitional period from capitalism to socialism. It is a dictatorship in that political power is used to abolish the social relations of production which create profit and rent. Since Marx assumed that the proletariat would constitute the overwhelming majority of the population as the polar class to the *bourgeoisie*, the dictatorship of the proletariat was conceived as a form of workers' democracy. It was not conceived as a dictatorship of the minority or of a political party, but of a social class, and emphatically not the dictatorship of a political party over the proletariat. This is evidenced by the language of the *Communist Manifesto* and by Engels' public reference to the Paris Commune as an illustration of a proletarian dictatorship.

After the Russian October Revolution of 1917 the meaning of "the dictatorship of the proletariat" changed. Lenin, Trotsky and Stalin declared that it represented substantially the dictatorship of a minority political party. This party consists of the self-designated vanguard of the proletariat, although its members need not be proletarian in origin. It speaks and acts for the whole of the proletariat and ultimately for the whole working class. The latter, however, cannot freely accept or reject its leadership since no rights of opposition to the ruling party are recognized. To add to this shift in meaning, it should be observed that although the U.S.S.R. was officially proclaimed to be a socialist society without any classes, it continued to be characterized as a dictatorship of the proletariat. Under such circumstances the term proletariat became

more of a slogan than a precise designation of a social or economic group. Because of these ambiguities, the term must always be interpreted in relation to the specific historical situation and the concrete social context in which it is employed. See BOLSHEVIKS; COMMUNISM; COMMUNIST PARTIES; MARXISM; SOCIALISM.

PROLOGUE, a prefatory piece of writing, usually composed to introduce a drama. The Greek *prologos* included the modern meaning, but was of wider significance, embracing any kind of preface. In Greek drama, a character, often a deity, stood forward or appeared from a machine before the action of the play began, and made from the empty stage such statements as it was necessary that the audience should hear. It was the custom to explain everything that had led up to the play, the latter being itself, as a rule, merely the catastrophe following on the facts related in the prologue. The importance, therefore, of the prologue in Greek drama was very great. With Euripides, as has been said, it takes the place of "an explanatory first act." On the Latin stage the prologue was often more elaborately written than in Athens, and in the careful composition of the poems which Plautus prefixes to his plays we see what importance he gave to it; sometimes, as in the preface to the *Rudens*, Plautus rises to the height of his genius. Molière revived the Plautine prologue in the introduction to his *Amphitryon*; Racine introduced Piety as the speaker of a prologue to *Esther*. The tradition of the ancients vividly affected the early English dramatists. Not only were the mystery plays and miracles of the middle ages begun by a homily, but when the modern drama was inaugurated the prologue came with it, directly adapted from the ancient practice. Thomas Sackville prepared a sort of prologue in dumb show for his *Gorboduc* of 1562; and he also wrote a famous *Induction* (practically a prologue) to a miscellany of short romantic epics by diverse hands. In the Elizabethan drama the prologue was very far from being universally employed. In the plays of Shakespeare it is rare. After the Restoration, prologues became obligatory. They were always written in rhymed verse, and were generally spoken by a principal actor or actress. See also EPILOGUE.

PROME, a town and district in the Pegu division of Lower Burma. The district occupies the valley of the Irrawaddy River, between Thayetmyo district on the north and Henzada and Tharawaddy districts on the south. Area 2,953 sq.mi. (7,648 sq.km.). Pop. (1962 est.) 496,960. There are two mountain ranges, the Arakan Yoma and the Pegu Yoma. The former extends along the western side. The portion of the district on the right bank of the Irrawaddy is broken up by thickly wooded spurs running south-eastward. Cultivation is confined to the parts adjacent to the river. On the eastern side lies the Pegu Yoma, and north and northeast of the district its forest-covered spurs form numerous valleys and ravines, the torrents from which unite in one large stream, the Na-win Chaung. The staple crop is rice, but cotton and tobacco are grown, while the custard apples are famous. The forests yield teak and cutch.

Prome town, capital of the district, lies on the Irrawaddy, 161 mi. (259 km.) NNW of Rangoon. Pop. (1953) 36,997. The Burmese refer to Prome as Pyi, which means "the capital," but the actual site of the old city, known as Sri Ksetra ("city of splendour"), is five miles to the southeast of Prome and is now known as Hmawza. Excavations there, started in 1907 by Gen. Léon de Beylié and later by Taw Sein Ko, revealed a Pyu culture quite distinct from both Mon and Burmese. The Pyus were one of the earliest of the Tibeto-Burman stock to come into Burma after the 3rd century. They occupied the Irrawaddy valley from Shwebo to Prome. Sri Ksetra was probably built in A.D. 638 by Hari Vikrama. It was the capital of a new dynasty, the Vikrama, which inaugurated a new era called Sakarac, a term that is still in use. The city was almost circular and its walls enclosed an area of about 18 sq.mi. (46 sq.km.). The northern part seems to have

consisted of paddy fields so that it could withstand a long siege. The city however fell early in the 8th century. The Pyus retreated north and built another city that was destroyed in A.D. 832. The Burmese came into Burma only after this; they learned to respect the Pyu civilization and have continued to call the old Pyu centre Pyi.

PROMETHEUS, in Greek cult "the fire-bearing Titan god" (Sophocles, *Oedipus at Colonus*, 55). The fundamental notion about him is that he stole fire from the gods for the benefit of mankind. Like the Norse Loki, he was a trickster as well as a fire-god, and his intellectual side was emphasized by the apparent meaning of his name, "Forethinker."

In Hesiod's *Works and Days* (700 B.C.?) his story is told to explain why men must toil for their living: the gods have "hidden livelihood" from men because Prometheus deceived Zeus. Zeus did not intend that men should have fire but Prometheus ("Fore-sight") stole it for them anyway. In return Zeus had the woman Pandora (*q.v.*) created and sent her down to Epimetheus ("Hindsight"), who, though warned by Prometheus, took her in and only afterward realized what woe he had brought upon mankind. Before this, men had lived free from evils and hard work and disease, but Pandora took the great lid off the jar and all these things flew out to wander among mankind. Hope alone stayed within. "So impossible is it to escape the will of Zeus."

The context of this story makes it clear that in Hesiod's mind Prometheus' theft of fire brought with it the working of metals, and metals meant weapons, and weapons meant violence and greed. Though Prometheus' gift brought civilization, it was a "heroic" civilization and Hesiod wanted no part of it. The figure of Pandora, with her jar full of evil and toil and disease, serves to express both the attractiveness and the ultimate hopelessness of civilization. By sending Pandora "as the price of fire" the gods "hid livelihood." As Hesiod saw it, fire and civilization had ended by blighting both men and nature.

In the Hesiodic *Theogony* Prometheus himself is punished. Zeus bound him and set an eagle upon him to devour his immortal liver, constantly replenished. Later he permitted Heracles to kill the eagle, wishing to do his son honour. "Seeking to rival Zeus in counsel," Prometheus had tried to trick him into accepting the bones of sacrifices instead of the meat, which would then be left for men. Zeus saw through the trick, but chose the bones—which became his portion from then on—"because he meditated evil for men." Thereupon he withheld fire, Prometheus stole it, and Pandora was sent to men as in the earlier account, "a bad thing as the price of a good one." "So impossible is it to deceive or circumvent the will of Zeus. Not even the son of Iapetus, kindly Prometheus, escaped his anger, but under Necessity, wise though he is, the mighty bonds restrain him."

In this account the theft of fire is merely one example of Foresight's doomed attempts to have the better of heaven, and Pandora is simply the first woman, expensive, hard to live either with or without, but bringing no jar of evil, toil, and disease. The inner connection between the theft of fire and the coming of Pandora is gone—this poet has no quarrel with technical advances—but all the same, in the bound Prometheus he has, with some help from the *Odyssey* (*cf.* Tityus in Hades), created the great image of human intelligence agonized and helpless in the grip of necessity which has fascinated many poets since.

In working out this theme Aeschylus in *Prometheus Bound* makes Prometheus not only the bringer of fire and civilization to men but their preserver. Zeus had intended to destroy them and create a new race, but Prometheus prevented this and gave men not only the means of survival but all the arts and sciences. For this Zeus has him chained to a crag in Scythia at the ends of the earth. But he knows what Zeus does not, the marriage which will cause Zeus's downfall, and he keeps the secret as the price of his release, though Zeus blasts him down to Tartarus at the end of the play. Though the rest of the trilogy is lost, we know that Prometheus was restored to the upper world still chained, this time with the eagle to torment him, that Heracles came and shot the eagle, and that finally the prisoner was set free, with intelligence and

power, human hopes and the will of heaven reconciled at last. Hesiod and Aeschylus provide the basis for most of the many other treatments of Prometheus. When the gods created men and animals out of earth, according to Plato (*Protagoras*, 320 ff.), Prometheus put into man fire stolen from Athena and Hephaestus to compensate for Epimetheus' having used up the simpler means of survival on the animals. This could account for the tradition, which seems to be later, that Prometheus created man.

See H. J. Rose, *A Handbook of Greek Mythology* (1928).

(G. E. Dκ.)

PROMETHIUM is a metallic element of the rare-earth series, symbol Pm, atomic number 61. It is unique in that it is the only rare-earth element that does not occur naturally (except possibly in extremely small traces resulting from the spontaneous fission of uranium in uranium ores). However, fission-product promethium is found in quantities sufficient for identification and study in the residues from nuclear reactors; it is also prepared by slow neutron bombardment of an isotope of neodymium, Nd¹⁴⁶. No stable isotope has been found; of the 14 unstable species known, the longest-lived is Pm¹⁴⁵, with a half-life of 18 years. Because of the short half-lives of its isotopes, promethium probably does not occur in nature in concentrations which would permit its chemical separation.

The first conclusive chemical proof of the existence of promethium was obtained in 1947 by J. A. Marinsky, L. E. Glendenin, and C. D. Coryell, who isolated the radioisotope Pm¹⁴⁷ (half-life 2.7 years) from atomic fission products obtained at the Oak Ridge (Tenn.) research site. Identification was firmly established by spectroscopy. The discovery completed the search for missing rare-earth elements. A number of investigators in the past had claimed to have proved the existence of element 61 in naturally occurring rare earths; among the names they applied were *ilimium* and *florentium*. The name promethium is derived from Prometheus, who in Greek mythology stole fire from heaven and gave it to mankind—an appropriate name, since the element comes from the fierce fires of the atomic furnace.

The properties of promethium appear to be those of a typical rare earth. It is trivalent in its compounds and solutions, most of which are pink or rose in colour. It absorbs ultraviolet and visible light in discrete sharp bands which are useful for quantitative analyses. The ion is paramagnetic due to unpaired electrons. The metal has been prepared by the same methods used for light rare earths (see *PRASEODYMIUM* and *NEODYMIUM*). The metal melts at 1,080° C and resembles the other rare-earth metals both chemically and physically. Though promethium salts have been used for miniature batteries, the main use of the element is in research. See also *RARE EARTHS*.

(Ld. B. A.)

PRONGHORN (*PRONGBUCK*, *PRONGHORNED ANTELOPE*), the sole living representative of the family Antilocapridae, which earlier evolved numerous and varied forms found as fossils in North America. Called the "American antelope"—though it is not a true antelope (*q.v.*)—the pronghorn (*Antilocapra americana*) stands up to 3 ft. high at the shoulder; it is reddish-brown, with white underparts, white flanks and cheeks, two white bands on the throat, and a large circular white signal patch on the rump. The tail and the short mane on the upper neck are dark brown. The horns are erect and diverging and branch into two prongs, the longer curving backward and inward, the shorter projecting forward; the horny sheaths are shed and renewed annually but the bony cores, on which the front prong is barely represented, are retained. Pronghorns are fleet and inhabit open plains and semideserts; they formerly lived in immense numbers from Alberta to Mexico, at their peak population numbering perhaps more than 40,000,000. After a most having been exterminated in the early 20th century, they have responded well to conservation practices aimed at their recovery.

See A. S. Einarsen, *The Pronghorn Antelope and Its Management* (1948).

(L. H. M.)

PRONUNCIATION. In a most inclusive sense pronunciation is the form in which the elementary symbols of language, the segmental phones or speech-sounds, appear and are arranged in patterns of pitch, loudness, and duration. In the simplest model

of the communication process in language—ENCODING . . . MESSAGE . . . DECODING—pronunciation is an activity, shaping the output of the encoding stage, and a state, the external appearance of the message and input to the decoding stage. It is what the speaker does, and what the hearer perceives and, so far as evaluation is called for, judges. It is so basic to language that it has to be considered in any general discussion of language or particular discussion of the English language, etc.

In a narrower and more popular use, questions of pronunciation are raised only in connection with value judgments. Orthoepy, correct pronunciation, is parallel to orthography, correct spelling. "How do you pronounce [spell] that word?" is either a request for the correct pronunciation (spelling) by one who is unsure, or a probing for evidence that the respondent does not pronounce (spell) correctly or speaks a different dialect or has an attractive or repulsive idiosyncrasy in his speech. Only mispronunciations are noticeable, therefore distracting; they introduce "noise" into the communication system to reduce its efficiency.

The Act of Pronunciation.—The production of speech is basically the same as the production of any other sound, with an apparatus for setting up vibrations in the air which affect the organs of perception in the ear of the hearer. (See *VOICE*.) The sound of speech differs from the sound of a noise- or music-producing instrument because the organs of speech can change the quality of the sound produced as well as alter its pitch, loudness, and duration. It is as though speech were played on a number of instruments, one for *ah*, another for *sh*, etc., each one in operation for only a few hundredths of a second at a time, all smoothed out into a continuous flow.

The term pronunciation is usually restricted to differentiation in the qualities of the speech sounds and in stresses and tones where pertinent. Voice quality, such as nasality or breathy voice, is not included unless it is a differentiating feature of the sounds of the language. The term is only vaguely applied to stretches of speech longer than a word, such as the intonation of sentences, and it may be said that someone has an excellent pronunciation of a language but his tune is all wrong.

The study of the production of speech is phonetics, often defined as the science of pronunciation. (See *PHONETICS*.) It is here to be noted only that, whereas adjustments of the organs of speech may be monitored by the speaker's tactile, kinesthetic, and even visual senses, primary monitoring is by ear, and any hearing child learns to speak the language of the group with which he grows up, without any directions as to articulation. For some languages, *e.g.*, English, the consonant articulations are comparatively neat and stable, the vowel articulations less so. For other languages, *e.g.*, Spanish, it is the other way around. For some languages the general pattern of articulation is comparatively precise, for others not so. The pronunciation of English cannot be made better, but only obnoxiously conspicuous, by a precision of articulation which is contrary to the genius of the language.

The System and the Pronunciation.—The systematic function of pronunciation is to make those distinctions among the consonants and vowels in the flow of speech, and, for some languages, among quantities, stresses, and pitches, which have to be made in order to distinguish meanings in sentences. The simplest illustration shows one critical point only in the sentence—*e.g.*: "He's been writing/riding." "Ich will die andere Seite/Seide" ("I want the other page/silk"). "Il est tanné/damné" ("He is tanned/damned"). "No es nata/nada" ("It is not cream/It is nothing"). For the pronunciation to satisfy the ear of the native speaker, however, the way in which the distinctions are made (*i.e.*, the qualities of the consonants and vowels and the way in which they are run into the flow of speech) is fully as important as the fact that the distinctions called for are made. In the terminology of linguistics, the systematic function is said to be phonemic and the qualitative propriety phonetic.

For all examples above the phonemic statement is very simple: /t/ ≠ /d/; *i.e.*, the distinction between /t/ and /d/ may be used to mark a distinction in meaning in English, German, French, or Spanish. By other similar operations each /t/ and /d/ can be shown to be in opposition to all other phonemes in its language. It is

general practice, although not strictly phonemic, to group phonemes into phonetic-named classes and identify as intersections of classes (see below).

The description of the phones, or speech sounds as sounds, is another matter. These [t]s (i.e., phones rather than phonemes) are voiceless except that in some varieties of English the [t] in this environment is voiced. In German it is aspirated, in French and Spanish not. The [d]s are stops except that the Spanish phone is a fricative. Both are strictly alveolar in standard English, dental with the tongue touching the edges of the incisors in Spanish, and differently intermediate for German and French. There are other small differences in articulation in this environment and still others in other environments. It is possible to describe phonetically close to 90 varieties of [t] for General American English; some of them may be got at only by straining the apparatus of description, but for most of them any different articulation will produce a pronunciation not quite right.

Language Systems.—The pronunciations of various languages may be compared in a general way by noting the inventory of phonemes by classes.

English has one of the most frequently occurring stop systems, /p/ /t/ /k/, with an affricate, /tʃ/, *pin, tin, kin, chin*. Other languages have as few as two stops (Hawaiian) to as many as six (Yuma), with none to three affricates. The English fricative or spirant system has four, not corresponding places, /f/ /θ/ /s/ /ʃ/, *fin, thin, sin, shin*; Scots has also a /x/, *loch*, as in older English and present German and Spanish. Some languages have uvulars or pharyngals. English has a double, tense-lax, system for obstruents, /p/ /b/ . . . /tʃ/ /dʒ/, *mop, mob . . . mesher, measure*. Chinese has an aspirated-unaspirated system for stops, Hindi four kinds of stops. The English and German nasal systems correspond to the simple stops, /m/ /n/ /ŋ/, *some, sun, sung*. French and Spanish have /ɲ/ rather than /ɲ/, *peigne, piña*, other languages none to four nasals. The *l* and *r* types are not contrasted in Japanese and furnish two phonemes each in Castilian Spanish. English /r/ may well be put into the semivowel system, /j/ /ɹ/ /w/ /h/, *yea, ray, weigh, hay*. Russian has a double system of plain and palatalized consonants, Italian a complete system of geminates.

Spanish has a five-vowel system, /i/ /e/ /a/ /o/ /u/. Tagalog has three vowels. The American English system is variously interpreted as 9 simple vowels plus complex vocalic nuclei or as about 15 vowels plus diphthongs. German and French have front-rounded and French has nasalized vowels, as English and Spanish do not. Some languages have long vowels contrasting with short, as Middle English did—hence the terms “long *a*,” “short *a*,” etc., now quite meaningless.

There are also systems which include types strange to English and the nearby languages. Burmese has vowels with breathy voice in contrast to not breathy. Ibo has inspired voiced stops. Georgian has glottalized stops (air-compressed by raising the closed glottis). Hottentot has clicks (with mouth-air suction; see **CLICKS**). There are many tone languages for which the relative pitch level or direction of pitch turn of a syllable is part of the phonemic system and pronunciation as distinguished from the intonation. Chinese is the best-known example, and there are other Far Eastern and many African and American Indian tone languages. Swedish and Norwegian have a limited tone system.

Dialects and Standards of Pronunciation.—In a technical sense, without deprecatory or romantic connotations, a dialect is any form of a language peculiar to any community of speakers of the language. (See also **LINGUISTICS: The External History of Language: Formation of Dialects**.) Every native speaker speaks a dialect and every native hearer puts the man he hears in a pigeonhole cross-labeled by region and social class. A language is the sum of its dialects or a generalization based on them.

For the hundreds of local dialects to be found wherever a language has been spoken by many people over a large area for a long time, the pronunciation is bound up in a total complex, including also morphology, syntax, and lexicon. The attitude toward dialect in this sense—avoided as a lower-class marker in Great Britain, used by many upper-class speakers in Germany in inti-

mate situations—is an attitude toward the dialect as a whole, not particularly the pronunciation. The emphasis on pronunciation in dramatic literature, as in Shaw's *Pygmalion* and *My Fair Lady*, is presumably to suggest the dialect without making it incomprehensible. In the United States, where there are few strictly English dialects of this sort—as there are, for example, few such dialects of Spanish in Argentina—the nearest equivalent is the contamination of English by other languages.

Among regional upper-class dialects of the standard language distinctions are made primarily in pronunciation and intonation, what David Abercrombie calls “accents” rather than “dialects,” where the morphology and syntax vary almost not at all and the lexicon not much more. Standard English is differently pronounced in London and Edinburgh and in Chicago and Sydney, standard French in Paris and Marseilles and Quebec, standard Spanish in Madrid and Buenos Aires, standard German in Berlin and Munich. In some cases the phonemic system varies, as notably among English, Scots, and American dialects and those of Spain and Central and South America.

There are of course dialects intermediate between strictly local and strictly regional in the larger sense and between lower-class and upper-class. Pronunciation is sometimes a more, sometimes a less, prominent sign. In the United States, where “accent” and “dialect” are interchangeable terms and “dialect speaker” does not occur, pronunciation is the primary regional marker, what is called grammar the class marker where there is any.

The concept of a standard pronunciation—i.e., of one pronunciation of the standard language with greater prestige than others—seems to be common to all languages except those with so few speakers that the question does not arise. For French the standard is said to be “celle de la bonne société parisienne” (“that of high Parisian society”); for Spanish, “la que se usa corrientemente en Castilla en la conversación de las personas ilustradas” (“that which is commonly used in the conversation of cultivated Castilians”). For German the base is a style of speech developed for the stage, which serves as “ein Ideal, das als Ziel und Maßstab für alles gebildete Sprechen aufgestellt ist” (“an ideal that is established as goal and norm for all educated speech”). In all these cases the standard may be modified in practice; few Germans outside theatrical circles speak the regionless ideal standard, and Argentinians are proud of their non-Castilian standard.

The situation is different in Great Britain, where there is now a nonregional, strictly upper-class dialect of enormous prestige, Received Pronunciation, spoken by those who learned it at home and in the public schools. It is said that only an RP speaker can surely identify RP speech. For those outside the RP circle, the regional “accents” are a practical standard. In the United States there can hardly be said to be, and is said not to be, any definable standard. With J. S. Kenyon's “familiar cultivated colloquial” as a reference, some Americans speak of Eastern, Northern or General, and Southern standards. American English is as loose a term as British English.

Changes in Pronunciation.—It is accepted as a truism that pronunciation changes more or less continuously. Since there is no inheritance of language and every child has to learn from what he hears about him, it is to be expected that the learning will not be perfect in every detail. Most individual eccentricities are discouraged by the conservatism of the community and are not passed on to the succeeding generation. By and large the language corrects itself. From time to time, however, what might be called a mistake in pronunciation seems to catch on and a change gets under way, sometimes so gradual in development as to be recorded only in retrospect.

A change which affects one phone or a group of related phones without apparent influence by the environment is known as isolative or independent. Thus the Great Vowel Shift in English was a gradual change in the pronunciation of all long vowels wherever they occurred. (See **ENGLISH LANGUAGE: Modern English: Phonology**.) The only explanation that can be made of this shift is that it did not materially alter the system, either as to number of phonemes or distribution. The new diphthongal vowels, in *line* and *cow*, were not easier to produce than the simple vowels

that were lost, to be reintroduced later in *calm* and *law*. For this and other isolative changes in English and in other languages, it is hard to say why they took place or why they happened when they did.

Changes which affect certain phones or groups of phones in certain environments only are known as combinative or dependent. The general pattern is one of ease of pronunciation, the speaker tending to make the least effort; this tendency is countered by the demand of the hearer for easy intelligibility. Thus the *ɨ*-umlaut or *i*-mutation in English and other languages results when the speaker, anticipating the articulation for a front [i] or [j] in the next syllable (later lost), shifts the articulation of the vowel in question from back to front; thus *fill* (cf. Gothic *fulljan*) beside *full*.

The most obvious effort-reducing change is assimilation of consonants. The term is itself an example, from *ad-* "to" + *simil-* "similar," the forms *adsimil-* and *assimil-* both attested in classical Latin. Assimilations may or may not be accepted by the community. Thus [f], representing a reciprocal assimilation of [s] + [f], prevails in *issue* in America but [sj] in England; [ɛ] is usual in *literature* but [tj] occurs, sometimes taken as a sign of affectation; *can't you* may be pronounced with [tj] or [ɛ], the latter subject to social sanctions. Most such assimilations merely shift the distribution of phonemes—more /f/'s and fewer /s/'s, etc. But when [z] + [j] became [ʒ], *vision*, the new phoneme /ʒ/ filled a gap in the English system which John Hart had pointed out half a century earlier.

The change in English which had the greatest effect was the obscuration of vowels in unaccented syllables. As direct consequence the neutral vowel came to be the most frequently occurring syllabic in the language, and as indirect consequence many inflectional endings earlier marked by vowel contrasts became non-discriminating and then were simplified or lost.

The number of reconstructions in the system of English brought about by changes in pronunciation is reported, by C. F. Hockett, as approximately 100.

Graphic Representation of Pronunciation.—The principal way of holding pronunciation still for examination or for transmitting it through time and space is alphabetic, or syllabic, writing. (See ALPHABET; WRITING.) The written word is not coordinate with, much less superordinate to, the spoken word. Chinese 石 may correspond in a way to English *stone*, but the one is a first-order symbol, the other a second-order symbolization of the composition of a first-order symbol.

Chinese	thing}	ideograph symbol	
	or idea }	spoken symbol	
English	thing}	spoken symbol	alphabet symbols
	or idea }		

In a way it may be said that any language can be phonemically written with any alphabet and that, as Bloomfield said, "A language is the same no matter what system of writing may be used to record it, just as a person is the same no matter how you take his picture." (Leonard Bloomfield, *Language*, p. 21, Holt, Rinehart and Winston, Inc., New York, N.Y., 1933, © 1961.) But the writing of quite dissimilar languages, and it is not to be expected that they will work equally well for all. Nor does writing often keep up with changes in pronunciation. Thus, although the early writing of English in an augmented Roman alphabet was adequate, most of the later phonemic changes have not been recorded. Moreover useless new spellings were introduced, by Anglo-French scribes, and analogical and etymological spellings—some of the latter encouraging spelling pronunciations. Similarly for other languages, if on a smaller scale, the long-established writing has come to be less than satisfactory. The languages now having adequate phonemic writing are those which have recently adopted a new alphabet or reformed the spelling.

To correct the deficiency, individuals and organizations have developed phonetic alphabets, either for spelling reform, in English

quite unsuccessful, or for special purposes such as language learning. Nonalphabetic systems with symbols descriptive of articulations, such as that of Alexander Melville Bell, have not found favour, although some such symbols are used for teaching the deaf.

Teaching and Learning Pronunciation.—It is only late learning situations that call for comment: the correction of speech defects, the replacement of a class-inferior by a class-superior pronunciation, and the acquisition of a new language. The last may be taken as typical.

The new language learner must use some kind of pronunciation; apparently it is impossible, perhaps with rare exceptions, for one to hold in mind a language form without an aural image of the form as whole, even if his only practical concern is a reading knowledge of the new language. It is only trivially more difficult to use a reasonably good pronunciation of the language being learned than it is to get by, as many have done, with an imagery of pronunciation based on the language of the learner.

When the learner expects to use the language in the ordinary way it is more readily apparent to him that pronunciation is important. The proximity of England to the continent and the use of English in former British colonies undoubtedly accounts for the fact that more apparatus is available for teaching-learning an RP type of pronunciation than for any other standard pronunciation of English. Techniques for teaching the pronunciation of English and many other languages have been enormously developed in the United States since World War II. (See also FOREIGN LANGUAGES, TEACHING OF.)

Any plan for teaching pronunciation tends to be dominated by a phonemic approach, primarily concerned with making the distinctions necessary for intelligibility; or a phonetic approach, aiming at a pronunciation that will satisfy the native ear. The difference is more in the materials supplied as teaching aids than in the actual instruction supplied by a master who can fill in the detail for the one plan and the synthesis for the other. Use can be made, especially for unusual languages, of linguistically naïve native informants, the theoretical control being in the hands of a linguist who may have more understanding of the system of the language than skill in speaking it. Phonetic alphabets are in general use, although neither in all cases necessary nor by any means to be taken as having any magic power. For mass instruction, recordings are now generally available, their utility greatly increased when the apparatus provides for recording-playback of the student's imitation for immediate comparison.

Modern Investigation of Pronunciation.—The study of the distribution of linguistic forms over an area is known as linguistic, or dialect, geography. (See DIALECT GEOGRAPHY.) The usual systematic technique is direct investigation by trained field workers, who go into selected communities and interview typical informants according to a fixed scheme, recording the findings in phonetic notation. Postal questionnaires may be used rather than, or as supplementary to, direct interviews. Tape recordings are usually made when possible, to serve either as the basis for phonetic interpretation or as a supplementary check. The number of communities investigated, the number of informants used in a community, and the length and coverage of the work sheets vary according to special conditions, especially the number of investigators and amount of funds and time available. Findings are shown on maps or in tables.

Large-scale investigations are rarely limited to data on pronunciation, and the number of strictly phonetic items on a work sheet may be small. But as a rule (e.g., in the *Linguistic Atlas of New England*) the phonetic recording of morphological, syntactical, and lexical data is trustworthy and can be used as data on pronunciation. The European atlases have been primarily concerned with local dialects. American investigations, necessarily concerned more with local variation of the standard language, include some cultured informants.

Some variations on the general plan of investigation are noteworthy. One is the quantitative investigation of a limited number of items with many randomly or systematically selected informants in a community, the results expressed in percentages. Another is the use of a single informant on the basis of whose speech

the pattern of pronunciation, the phonemic system, and other features of the dialect or language are described. The last method, particularly useful when informants are hard to come by and more frequently used for individual studies than in large-scale undertakings, has its extreme form in the investigator's use of himself as informant. Another, *Phonometrie*, is the instrumental analysis of field tape recordings and measurement of certain features on the basis of which can be made fine quantitative distinctions quite impossible to ear analysis and useful for marking significant boundaries. See also PHONETICS; LINGUISTICS.

PROOFREADING, the process of correcting for the press printed proofs of articles, books or other matter before publication. That the proofreader's profession goes back to the early days of printing is proved by reference to a corrector of the press in a book printed by R. Pynson in 1530 (the word proofreader seems originally U.S.). A Pynson contract of 1499 also held the author finally responsible for correction of proofs. In modern practice proofs are made first in galley (usually three or four pages unbroken on a long sheet), the first rough proof usually being corrected by the printer before being sent to the publisher and ultimately to the author. Page proofs and galley proofs frequently bear queries that show the proofreader's skill involves not only seeing that there is an exact correspondence between the copy given to the printer and its printed form, but also the catching of errors of fact. Lawsuits between printers and authors, and lists of errata, author's apologies and complaints at not seeing proof in printed books were common through the 15th, 16th, 17th and 18th centuries and are not unknown in modern publication.

Marks commonly used in proofreading follow:

☞ Delete	<u>em</u>	Em dash
☞ Delete and close up	<u>en</u>	En dash
↺ Reverse	;	Insert semicolon
○ Close up	Ⓢ	Insert colon and en quad
# Insert space	Ⓢ	Insert period and en quad
¶ Paragraph	?	Insert interrogation point
□ Indent one em	?	Query to author
⌊ Move to left	~	Use ligature
⌋ Move to right	Ⓢ	Spell out
⌋ Lower	tr	Transpose
⌋ Elevate	wf	Wrong font
^ Insert marginal addition	bf	Set in <u>bold face</u> type
∨A Even space	rom	Set in <u>roman</u> type
X Broken letter	ital	Set in <u>italic</u> type
↓ Push down space	caps	Set in <u>CAPITALS</u>
≡ Straighten line	sc	Set in <u>SMALL CAPITALS</u>
Align type	lc	Set in <u>lower case</u>
^ Insert comma	k	<u>Lower-case letter</u>
∨ Insert apostrophe	stat	Let it stand
∨ Insert quotes	no ¶	Run in same paragraph
= Hyphen	ld	Insert lead between lines

PROOF SPIRIT, the term applied to those standard mixtures of ethyl alcohol and water that form the basis of customs and excise duties in many parts of the world. The term is variously defined. In the United States proof spirit, by federal regulations, is an alcoholic liquor one-half of whose volume is alcohol of a specific gravity of 0.7939 at 60° F (15.6° C), referred to water at 60° F as unity. At 60° F, proof spirit has a specific gravity of 0.93426 (*in vacuo*); 100 parts by volume of the liquor consists of 50 parts of absolute alcohol and 53.73 parts of water; the difference of the sum of the parts of alcohol and water and the resulting 100 parts of proof spirit is caused by the contraction that takes place when alcohol and water are mixed. The specially designed hydrometers used in determining the alcoholic strength of aqueous solutions read (at 60° F) 0 for water, 100 for proof spirit (also called 100 proof), and 200 for absolute alcohol.

In Great Britain the Spirits Act of 1816 gave for the first time a legal definition of proof spirit as "that which at the temperature of 51° F weighs exactly $\frac{1}{3}$ of an equal measure of distilled water." Subsequently, the temperature of the water was also established at 51° F (10.6° C). Later investigation showed that at 60° F proof spirit has a specific gravity of 0.91976, compared with water at the same temperature, and that it contains 49.28% by weight or 57.10% by volume of ethyl alcohol.

Spirits at strengths other than proof may be described as containing a percentage of proof spirit or as being overproof or underproof. The percentage of proof spirit is the number of volumes of proof spirit that can be obtained from 100 volumes of the mixture. Thus at 50° F, 100 volumes of absolute alcohol if diluted with water to proof strength give 175.35 volumes. It is therefore said to contain 175.35% proof spirit, to be 175.35 proof, or to have a strength of 75.35% overproof. (D. G. Z.; X.)

PROPAGANDA is the dissemination of information—facts, arguments, rumours, half-truths, or lies—to influence public opinion. As a systematic effort to persuade, it is an act of advocacy in mass communication, involving the making of deliberately one-sided statements to a mass audience. In this, it is not necessarily deceptive, although it is well known that one-sided presentations often spread and nourish false images by emphasizing only the good points of one position and the bad points of another. Hence one aim of public policy in popular government is to maintain a public forum in which the competing propagandas of political parties and interest organizations correct one another's lies and exaggerations. Although the fact of propaganda activity is old, the term is comparatively modern, deriving from the name of the organization set up in 1622 by the Roman Catholic Church to carry on missionary work, the Congregation for the Propagation of the Faith (*propaganda fide*).

Propaganda can be distinguished from other acts of mass communication with which it is closely allied. On the approach of a forest fire or a tidal wave, whole communities may dissolve into panic-stricken crowds or mobs whose rumours and cries are collective excitement, not propaganda. In the context of the society in which it occurs, the words reiterating traditional legends in a public ceremonial do not imply advocacy. Similarly, community indoctrination of the young with established beliefs, faiths, and loyalties is not ordinarily thought of as propaganda. However, it is advocacy to editorialize or to select the content of news reports, histories, textbooks, and other channels of communication for the purpose of influencing attitudes on controversial issues. (For some early examples, see HISTORY: *Roman Historians*.) When a government distributes a pamphlet on the care and feeding of babies, for example, the act is probably informative and instructive, not propagandistic, unless there is doubt about the authenticity of what is said, or the pamphlet is used for other than instructive ends—as winning goodwill for an official of the government. It is inquiry, not propaganda, to analyze contro-

You Young Yankee-Noodle, Strike Your Own Father!"

COMMON SENSE.

Of the Origin and Design of GOVERNMENT in general, with concise Remarks on the ENGLISH CONSTITUTION.

SOME writers have so confounded society with government, as to leave little or no distinction between them; whereas, they are not only different, but have different origins. Society is produced by our wants, and government by our wickedness; the former promotes our happiness *positively* by uniting our affections, the latter *negatively* by restraining our vices. The one encourages intercourse, the other creates distinctions. The first is a patron, the last a punisher.

Society in every state is a blessing, but Government even in its best state is but a necessary evil; in its worst state an intolerable one: for when we suffer, or are exposed to the same miseries by a Government, which we might expect in a country without Government, our calamity is heightened by reflection.

B

stitutions to moderate innovations or revolutionary change.

In political affairs it has usually been evident to the leaders of revolutions that they can greatly enhance their chances of success, as well as save soldiers and money, by using propaganda to win support for and induce obedience to a new regime. The foundation was laid for large and enduring empires when conquerors learned to convert rather than to exterminate the conquered.

Propaganda, being both elusive and cheap, is a favoured instrument of political oppositionists. The unification of Germany, Italy, and of every modern state was preceded and accompanied by the fervent promotion of national sentiment, often by persecuted minorities. The propagandists of social revolution have developed modern methods of persuasion to the highest pitch, working especially through party and auxiliary organizations.

In communities where the pursuit of knowledge is accepted for its own sake as well as in the serv-

versal doctrines for the sake of sharing enlightenment. For an example of such analysis, see **POLITICAL PHILOSOPHY** (see also **LIBERALISM**; **CONSERVATISM**). Private arguments among intimates are not propaganda unless they are part of a campaign to spread controversial viewpoints, which they often are.

The mass audience with which the propagandist is ultimately concerned is not only characterized by size, but by the impersonality and shallowness of the tie between the communicator and his audience. This is typical of advertising (*q.v.*) as paid publicity. It includes much, though not all, of the field of public relations (*q.v.*), whose aim is to manage the exposures of an individual or a group in order to obtain attitudes of effective support. Advertising, public relations, and propaganda often employ the same techniques and strategies and, operating in closely related fields, may often overlap. Since any act may influence mass opinion, an important part of total policy is calculating and managing the psychological impact of every policy. The most comprehensive term for this frame of reference is "propaganda" or "communication" policy. Directed against an enemy or opponent in wartime, or in cold war, this is "psychological" warfare (for history, examples, and techniques, see **PSYCHOLOGICAL WARFARE**).

The Propaganda Process.—In examining any specific propaganda campaign or describing the total flow of propaganda in any historical or contemporary setting, several questions arise. Who are the individuals or groups who initiate and execute these operations? What objectives are they trying to achieve? What are the boundaries of the situations in which they operate? With what potential assets (and with what constraining liabilities) do they begin? By what strategies are the objectives sought? With what outcomes and effects?

Participants.—In contemporary totalitarian states, the controllers of all permissible communication are governmental officials or the leaders of monopolistic political parties. At the other extreme are the pluralistic states, in which local officials often have great independence of central government, and in which competing political parties are supplemented by diversely controlled media of communication and by a network of pressure organizations recruited in varying degree from all save the least advantaged strata of society.

Objectives.—The objectives sought by the use of the propaganda instrument range from the protection of current values and in-

ice of practical ends, scientists and scholars have organized to win support for programs that combine substantial public and private assistance to research with nonintervention in the conduct of inquiry. Associations that speak in the name of science and learning often try to mobilize sentiment for or against the use of knowledge in military or other operations.

Where the production and distribution of wealth is in the hands of a private sector of society, the use of propaganda by organizations of commerce, industry, agriculture, and labour is a prominent feature of public life. In a dynamic economy the effective rules of the market, including the scope of government regulation and enterprise, are affected by the success or failure of promotional campaigns to influence third parties to give support to particular competitors. (See also **LOBBYING**.)

As interdependence increases with growing industrialization and urbanization, and as the risk rises of accidental death or injury and of infection from polluted air, water, soil, and food, propaganda operations strive to expand the jurisdiction and scale of the welfare state as it touches the safety, health, and comfort of the population.

With the expansion of industry and technology, the number of groups skilled in emerging occupations, the professions, and the arts is greatly multiplied. At the same time they come into conflict with those who have obsolete or obsolescent skills. All these groups rely heavily on propaganda to obtain training facilities, to attract talent, and to achieve favourable opportunities for employment. In these sectors, as elsewhere, conflicting and facilitating propagandas aid in delimiting the role of government in education and the arts.

As the extended-family characteristic of agrarian and folk societies gives way to smaller family units, public policy is affected by propaganda operations for or against the liberalization of divorce, the use of birth control, the protection of children from cruelty and neglect, and other problems of family relations.

In recent times, particularly, propaganda has been employed to upgrade the position of minority groups and depressed castes and classes, and also to exalt the image of particular individuals in public esteem.

At one time the great proselytizing religious sects of Buddhism, Zoroastrianism, Christianity, and Islam sought to expand at one another's expense. (See **MISSIONS**.) More recently, the rise of

successful secular political movements has inspired attempts to cultivate the ecumenical spirit among believers.

Whatever the objective pursued, no one denies that the success or failure of propaganda initiatives can usually be predicted from the assets at the disposal of the rivals. These assets are not exclusively economic. It counts heavily if the sponsors are politically potent, popular, upright, and respected. The crucial assets may be youth and vigour, especially when joined with an enlightened view of the problems at stake, and skill in communication. Or the crucial asset may be control of the government, or the power of censorship.

Propaganda may pursue distinctive objectives, or serve as an instrument of other policy aims. In foreign policy, for example, a distinctive objective at a given time may be in the field of propaganda policy, such as winning the friendship of the rank and file of the population of a foreign power. Friendship may be sought directly by news and comment, which are the instrumentalities on which propagandists most rely. In addition, cultural, educational, and scientific exchanges, and goodwill tours of outstanding athletes and entertainers may be employed. Other policy means may also be put at the service of the friendship objective. The diplomatic tool may be applied by upgrading a ministry to the status of an embassy. The economic tool may take the form of loans and subsidies. The military instrument may make new weapons available for defense.

Effects.—If a propaganda campaign is to have any chance of success it must at least reach the focus of attention of target audiences. Even under totalitarian conditions audiences are not altogether passive puppets. They may partially frustrate the official line by listening to or viewing official programs in a state of weary detachment, and by inventing or exchanging rumours at variance with the government's view.

Since the impact of propaganda is not necessarily immediate, any serious appraisal must be prepared to examine its middle- and long-range effects on perspective and behaviour. Not the least important impact is on the propagandists themselves. A leader may begin by entertaining private doubts about what he is saying, and end by believing it. This "feedback effect" may undermine his judgment of reality, and culminate in unexpected losses of power.

The Determiners of Propaganda.—Any provisional account of the propaganda process in particular campaigns, or in the aggregate, implies a comprehensive theory of causes and consequences. Systematic scientific studies of propaganda have been

closely identified with research on linguistics and the analysis of nonmaterial culture, the growth of psychoanalysis and other schools of psychology, and the rise of information theory in engineering, neurology, and genetics.

The most general conclusion about propaganda is that it increases whenever the equilibrium of society is threatened or upset, whether by political revolution, technological changes, marked population shifts due to mass emigration or immigration, or by rapidly rising or falling birth or death rates, or by other religious, social, or economic innovations or collapses. And it decreases with the restoration of the imperiled equilibrium or with the emergence of a new level of adjustment. This broad hypothesis can be made more specific in order to account for the use of propaganda, rather than coercion, on those occasions when social equilibrium is in danger. Viewing the available records of human culture it appears that both the practice and the study of propaganda are connected with the rise of urban civilization, notably in the valleys of the Nile, of the Tigris-Euphrates, and of the Indus. With the advent of cities the traditional ties of family and tribe were weakened to the advantage of territorially organized political communities, whether city-states, empires, or nations. The enduring impact of propaganda was increased by the institutionalization of civil government, and by the invention of writing, the making of records, and the growth of scribes in the city environment.

The first surviving studies of propaganda were manuals on state security. The use of mass means of communication for military purposes was advised in *The Art of War* in the 5th century B.C. Sun Tzu wrote that "In night fighting beacons and drums are largely used; in day fighting, a great number of banners and flags, and the enemy's eyes and ears are confounded." In the East Indian classic of statecraft, Kautilya's *Arthaśāstra*, it is noted that "Astrologers and other followers of the King should infuse spirit into the army by pointing out the impregnable nature of the array of his army." Secret agents should circulate among the enemy spreading rumours of their certain defeat. From Greco-Roman times come handbooks on how to win an argument or even how to win an election. The literature of propaganda includes manuals on converting the heathen, indoctrinating the young, instigating subversion, preventing subversion, obtaining gifts, and making sales. With the expansion of the social and behavioural sciences in comparatively recent times, "how to do it" manuals have been supplemented by scientific researches on the place of mass persuasion in the social process.

Propaganda—"the dissemination of information to influence public opinion," an "act of advocacy in mass communication"—has long (if not always) been used by inspired protagonists of change, from proponents of innovations in religious observances to advocates of lengthening the school day to supporters of public water supplies and sewerage systems, and by their opponents.

More and more it has been used consciously and with planning not only in the cause of revolution but, for example, in the introduction of the comprehensive school in Great Britain; in the American Medical Association's campaign against Medicare in the United States, and organized labour's campaign to support it; and in attempts to stamp out hooliganism in Hungary, Poland, and Czechoslovakia. It has formed the basis of campaigns to abolish capital punishment in the United Kingdom and New Zealand, to enforce traffic regulations in Argentina, and to promote the use of fertilizer in Iran. Fund-raising campaigns for churches and charities, the civil rights movement in the United States, the attempts to defend the Unilateral Declaration of Independence in Southern Rhodesia—all have employed propaganda as part of action for social ends.

In modern history the growth of industrialism has provided one of the greatest incentives to employ propaganda as an instrument with which to defend established patterns of culture or to spread innovation. Advertising, supported by propaganda (advocating, for example, the doctrine of Manifest Destiny [q.v.]), fanned the spirit of speculation which fed the reservoirs of capital upon which the expansion of commerce and industry depended. The advantages of large-scale production could be realized by the successful stimulation of consumer demand, and skilful and massive promotion stimulated hundreds of millions of buyers to change their taste in clothes, interior decoration, personal adornment, cooking, and amusement.

Since propaganda depends in part on accessible networks of communication, industrialism also facilitates propaganda by spreading literacy and general education, and by "the communications revolution" in mass media. In free countries the media themselves generate incentives to engage in and to foster propaganda, since some types of controversy stimulate circulation and circulation boosts revenue from the sale of space or time.

Other powerful modern incentives to the employment of propaganda have included the rise of Fascism and Nazism, the rise and spread of Soviet Communism and of Chinese Communism, and, markedly after World War II, the burgeoning nationalism of the newly emerging countries of the world.

The sheer size and heterogeneity of a population is of significance for propaganda. Even in totalitarian states a vast labour of internal persuasion is essential to overcome the bonds of attachment to the old, or the sentiments of fear, hatred, and confusion at the prospect of a new way of life. In Soviet Russia (after 1921) the full orchestra of poster, broadcast, and lecture was mobilized in a series of gigantic campaigns on behalf of literacy, proper care of tractors, and elementary habits of personal hygiene. In the latter 1960s the youth of Communist China were mobilized as the Red Guard in a massive campaign to wipe out all traces of Western influence in a "Great Proletarian Cultural Revolution."

The challenge of a new way of life has faced millions of the earth's population, especially since the end of World War II.

Propaganda has been a principal means of inaugurating new nation-states in the ruins of the colonial empires, of attracting aid from relatively modernized powers for the benefit of the underdeveloped nations, and of creating a sense of nationalism and overcoming internal predispositions unfavourable to nation-building. In many new or reviving countries, the balance has moved precariously between reliance on mass persuasion and resort to coercive means to expel foreign influence from every sector of society, as in Communist China. The revolution of rising expectations has often been exploited by the propaganda of rival groups to create the recurring crises of disappointment which have eventually culminated in take-overs after the model of totalitarian states. Persuasive methods have been best able to survive where traditional institutions, often as modified during the colonial period, have come to include institutions of freedom, whether free government, free market, free education, or free religious proselyting. Contrast, for instance, the early postindependence years of India and of many African states.

Summing up, the direction and volume of propaganda during any period depends upon the changing balance of incentives to influence or manipulate public opinion. Such factors as these are relevant: the intensity of the determination on the part of propagandists to introduce or to discourage change; the availability of mass media and the prevailing level of literacy and general education; the degree of discontent with the old and the difficulty of the new; the number of persons asked to change or to refrain from changing; and the depth of devotion to persuasion in place of coercion. Whatever arouses controversy is likely to foster propaganda until the incentives which sustain it are reduced and the rival methods of social action are tried, or discontent is dissipated without result (that is, catharsis occurs); or a new positive adjustment is made in prevailing social practice.

Strategy.—In view of the importance of strategy and tactics particular attention is given to principles that have been formulated. Proper strategy depends upon the overall frame of policy and the circumstances which favour or stand in the way of success.

When a comprehensive plan of social change is pursued by peaceful means, a major problem of strategic planning is whether to expedite success by making concessions of detail. At one time in China the Jesuits dressed like native scholars as a means of modifying the strangeness of the Christian mode of living. The pope decided to forego immediate advantages and put a stop to those practices. In the absence of unified command, Marxian Socialists split into many branches over the nature and timing of revisions. Leading revisionists softened or abandoned the doctrine of violent class struggle and entered electoral or cabinet coalitions; for example, in Germany and France in the 1920s and 1930s.

A related question of strategy is how far to concentrate upon the teaching and preaching of doctrine, and how far to go in using auxiliary appeals. Lenin insisted upon the necessity of propa-

ganda which he defined as indoctrination, and also of agitation, by which he meant the exploitation of concrete grievances (for a succinct account of the strategy see *BOLSHEVIKS*). In foreign missionary work, auxiliary activities, such as schools and child health clinics, became standard means of providing an indirect approach to prospective converts. Buddhist missions always encouraged charity, but it is reported that in China the translation of the Buddhist canon played a more important part than good works, since the translation aroused the curiosity of the scholar class.

Sometimes the task of propaganda is to prepare the way for

activities which, if fully disclosed in advance, would unquestionably fail. Before the seizure of power in Germany, the National Socialist strategy was to prevent a combination of Socialists, Communists, and conservatives which would have stalled their advance. Once the National Socialists were in power, the problem was transferred to the arena of world politics and became that of forestalling joint action by West and East while the country rearmed, occupied the Rhineland, absorbed Austria, partitioned Czechoslovakia, and began war against Poland. (For an account of the Nazi's exploitation of propaganda see NATIONAL SOCIALISM, especially the section *Psychological Methods and Theoretical Aims*.) Historians of the American propaganda of secession and independence from Great Britain, such as Evarts Greene, commented upon the skill of the leadership in carrying along many moderate persons who, though not desiring independence, had cooperated with the radicals to such an extent that they could not effectively withdraw.

The correlation of propaganda inside the frame of totalitarian policy involves many fundamental and, at first sight, paradoxical problems. One long-run objective of totalitarian policy is the substitution of ritual and ceremony for discussion and persuasion, hence of propaganda. A totalitarian state is a command state that swallows the whole society. The task of managing the media of communication under such conditions is to foster a world of fantasy wherein the hero at the top of the pyramid is the champion of all against the encircling forces of evil which, though powerful, cannot ultimately prevail. The propagandist does not use current happenings for news and comment, but for sermons and fables adorning the dogma as infallibly interpreted by the ruling machine. Only state- or party-controlled newspapers, books, and periodicals are permitted; all movies, plays, and radio and television broadcasts must support the propaganda message; and participation in parades, mass demonstrations, and political indoctrination sessions is compulsory. (For one sidelight on newspapers see *NEWSPAPER: Germany: The Hitler-Goebbels Press*.) Since commands from above allow no answering criticism from beneath, self-assertion is repressed or turned against the lower strata or the outside world. In such a garrison-police state leaders live in perpetual anxiety of losing control and require the reassuring balm of ritual adulation. All this is in vivid contrast to the operation of a free society which thrives on the clash of news and views.

Tactics.—The tactical problems of the propagandist are to adapt to the limits imposed by strategy. This implies that some policies, persons, groups, and institutions must be presented in a favourable light, while others are put at a disadvantage. Appropriate audiences and channels must be chosen to obtain the desired effects. An organization capable of the degree of devotion and expertness called for by the objectives sought must be assembled. The choices open to the tactician are ultimately to disseminate, to

withhold, or to modify a statement; to use, omit, or block a channel; to select or reject a person.

In deciding what to disseminate, the perspectives of the audience must be given careful consideration. The significant perspectives include conceptions of the self as identified with particular cultures, social classes, interest groups, and types of personality. For each component of the self of an individual or a group, various perspectives express value demands and expectations. In terms of cultural identity, for example, it is elementary for a skilful propagandist to show that his client loves and admires Southerners, for example, if the audience is Southern and that he is devoted to the Westerners, if the audience is Western. In addressing any group, the propagandist is fortunate whose principal can be presented as having the same status as the audience. The widest scope, no doubt, is in the assertion of common interests. Since the network of potential interests cuts across other social lines. Similarly the propagandist whose principal has highly personal appeal is able to exploit the charismatic predispositions of the audience. For each group the propagandist can emphasize the points that put his principal in the best light as a defender or extender of cherished values. Furthermore, it is possible to mobilize the expectations of the audience, as did the Spaniard conquistadors who seemed to fulfill an accepted prophecy when they appeared in Mexico (see MONTEZUMA II; QUETZALCOATL). The Spaniards were also favoured by a sense of crisis that was widely shared among the politically important elements of pre-Columbian society in America.

In deciding what to withhold, as distinguished from what to disseminate, the perspectives of the audience are crucially relevant to the tactician. If in a U.S. Information Agency target area the image of the United States is a nation of millionaires, documentary films of all components of American life may be substituted for films that depict the wealth of the nation. If the United States is perceived as materialistic and crude, the propagandists may play down the technological eminence of the U.S. and send art exhibits, symphony orchestras, and dance companies to try to change the image. Developing countries may resent the stereotypes of themselves that they find in industrially advanced societies, where they are often expected to be naked savages who live in tents or huts. Hence they attempt to reach the audiences of the industrial world with propaganda that leaves out the traditional clichés and shows dams under construction for electric power stations, and offices or high rise apartment buildings of glass and concrete.

In deciding whether to remain silent or to reply in response to an accusation, it is essential for the tactician to bear in mind that the pattern of conduct deemed appropriate or honourable varies widely according to the nature and source of the accusation, and the social context in which it is made. In some societies, only statements made by a member of the ruling class are taken with enough seriousness to warrant reply. Sometimes an accused leader, if innocent, is expected to display the utmost indignation in denying accusations. Elsewhere the badge of innocence is calmness. In many cases it is difficult to judge how much influence an adverse whispering campaign may have. When President Woodrow Wilson was the target of a campaign against his character, he declined to take any notice of it on the ground that it was false and that all who knew him understood it was false. He thought that it would give more currency and dignity to the "smear" if he replied in public than if he kept silent.

So far as facts are concerned, it is generally agreed that some facts cannot be successfully concealed from an audience. Hence it does less damage to release bad news promptly than to appear both unreliable and inefficient. Railroads learned to release news of accidents and the airlines followed suit. Often there are facts that are extremely disagreeable to both sides if disclosed. In bitter controversies it is customary for propagandists to try to obtain from intelligence services material that can be used privately to intimidate an adversary from spreading material that stigmatizes one's own candidate or cause.

Innumerable devices are at the command of the working propagandist for nullifying statements. Thus, a Soviet spokesman re-

marked that the Nazis had created a new category of war casualty, the "slightly killed." Wit, humour, calmness, the casting of doubt upon sources, the combining of favourable and unfavourable news, and the playing down of unfavourable statements are standard ways of modifying adverse references. Also there are ample means of inflating favourable statements by emphasis and elaboration.

A continuing tactical problem is how much to praise the self and how much to condemn rivals or enemies. Commercial competitors for the same large market usually refrain from attacking one another on the theory that doubt is cast upon the type as well as the brand of product. Unlike business propaganda, political propaganda tends to present politics as a drama in which the forces of good and evil stand opposed to one another. Revolutionary or urgent reform movements commonly try to induce a sense of guilt among opponents and self-righteousness among adherents, a technique used with marked success by, for example, Thomas Paine during the American Revolution (*see AMERICAN LITERATURE*). This tactic may succeed in provoking conflicts of conscience, since agreed value standards are applied to the disadvantage of the old and the advantage of the new.

In order to reach the mass audience, propagandists rely upon every medium of communication—oral, printed, pictorial, plastic, musical, or dramatic. Every new channel is promptly laid hold of. When the art of printing from movable type appeared in Europe, the printed word began at once to overtake oral media as a principal means of persuasion. In the 20th century the motion picture, radio, and television helped restore the spoken word to its former eminent position. Communication effects are sometimes sought with the aid of physical acts or devices which are not usually employed for the purpose. The act of killing is no ordinary method of communication, yet killing is spoken of as "propaganda of the deed" when political assassinations are carried out as a means of affecting attitudes. The building of the Berlin wall and the staging of marches and demonstrations are acts of propaganda.

In selecting media the propagandist keeps in mind considerations similar to those which apply to the choice of statements. If the problem is to win the support of the rich, powerful, and well-born, favourable mention in organs which they look down upon is no asset. If the aim is to win confidence among the masses, the task is to enlist the leaders and media which they trust. In some nonindustrial societies many members of the upper class may have been educated in other countries—in Japan, Western Europe, the U.S.S.R., or the U.S. They may look down upon the vernacular press and dismiss the authority of those who have not been educated abroad. Hence in the past the communication path of a rising local group in Asia, Africa, or Latin America might lead from Calcutta, Johannesburg, or Lima to London, Paris, or New York, and back to Calcutta, Johannesburg, or Lima.

In the choice of media, time considerations are important since if aims can be accomplished over long periods the more permanent media, such as scholarly books, magazines, and schools, have a significant role. If the goals are short run, the tactician must employ the existing communications network and rely on fast rather than slow media.

The audience of any established channel of communication has selected itself on the basis of predispositions which cannot be disregarded. During World War II, U.S. broadcasters to Germany quickly learned that crisis audiences differ from other kinds. Clandestine listeners who had risked their lives to hear news and comment from the outside world were furious when they tuned in on entertainment. Again, an audience expecting entertainment is irritated if it is given only news (or propaganda).

In the choice of personnel for propaganda work, one factor is emotional involvement. The history of propagandas of religion and revolution make it clear that dangerous propagandas need to be in devoted hands. Where less sacrificial considerations are at stake professional talent can be employed (in the same way that a lawyer takes over the claims of a client, not because the claim is right but because the client has a right to be heard). Political parties and movements have sought to develop or attract personnel that embody both qualifications, often most successfully:

reference has been made to Thomas Paine in the American Revolution; Nazism recruited a dedicated expert in Josef Goebbels (*q.v.*). But more and more frequently, in the United States at least, political parties, like private individuals, corporations, and associations, have employed professional public relations counsels or agencies to plan and direct propaganda and other aspects of their campaigns.

The 20th century has been notable for the rapid application of the social and psychological sciences to the problems of propaganda technique. It is standard operating procedure to pretest posters, labels, slogans, and other details before they are brought to the notice of the eventual audience. A pretest uses a small sample group. Posttests are utilized in the hope of evaluating the effectiveness of propaganda messages or channels. These tests are of the utmost diversity. They may be based on brief or prolonged interviews, upon the participant observation of behaviour, upon the analysis of a wide range of responses such as voting, giving, buying, selling, investing, joining, seceding, boycotting, striking, or attending. Methods have been devised to describe quantitatively the contents of the media of communication. Research is also done upon the control pattern that prevails in different countries, such as the degree of government monopoly or regulation, of private monopoly or competition.

Control.—It is impossible to scan the long history of attempts to control propaganda without being impressed by the power that men attribute to words. The fear of propaganda is fed by apprehension of the magical potency of language for the infliction of harm. These primitive attitudes continue to be an undercurrent in civilizations where the dominant attitude about language is not superstitious, but detached and managerial. The only control problems that disturb a modern totalitarian regime are questions of expediency in the realm of power. In nations where the dignity

BUDDHIST MONK BURNS HIMSELF TO DEATH IN SAIGON (1963) TO PROTEST ALLEGED PERSECUTION OF BUDDHISTS BY NGO DINH DIEM'S GOVERNMENT. AN ULTIMATE ACT OF PROPAGANDA

of man is upheld, the issues are more complex, since the institutions appropriate to a free society include freedom of information, propaganda, and political decision. Freedom is part of the respect due to the individual and is a condition of enlightenment and democracy. It is intolerable to totalitarianism, under which freedom of speech, freedom of the press, and free assembly are suppressed.

But freedom of utterance is nowhere without qualification. No free society fails to use community coercion against some forms of speech on the ground that the results endanger important values without corresponding gain. In controlling propaganda the aim is to safeguard news and comment without permitting incitement, which is an act of coercion. What shall be prohibited and by whom presents one of the most complicated and vexing problems that face free societies (*see, for example, CIVIL LIBERTIES, especially Mass Communications and Freedom of Expression*).

A consensus has arisen about the more extreme situations in which words become part of a coercive act. It is incitement when uniformed, armed, and trained formations are organized and begin to act. The appearance of these movements signifies that public order is dissolving and can be restored only by bringing coercion back into the hands of

organized government. This may, of course, be deferred until the end of civil war.

The thrust of recent discussions of international law and of treaty agreements has been in the direction of defining permissible limits on the use of managed communications for "aggressive" purposes. Among the classical terror campaigns were the synchronizing of mass media and of fifth column organizations to spread fright, suspicion, and confusion as a prelude to the seizure of power by the Nazis in Vienna and Czechoslovakia on the eve of World War II.

In internal affairs there are differences of opinion about the boundary lines of "incitement." What should public authorities do about statements provocative enough to arouse the anger of members of an audience whose religious, ethnic, or political sentiments are affronted? One view is that restrictions must be imposed when there is "clear and present danger" to public order. A more daring conception is that it is the purpose of a free society to maintain a kind of public order where coercive acts are not permitted in response to words, however offensive.

In time of war, popular governments are compelled to recognize that statements circulated by an enemy are part of the enemy's coercive activities. But what of statements uttered by members of the commonwealth who have no connection with a foreign power? Defenders of freedom assert that repressive measures against domestic propaganda must be kept at a minimum, with reliance for the protection of the body politic put upon the positive advocacy of the majority viewpoint, coupled with the disclosure of parallels, intended or unintended, between domestic propaganda and the line taken by the enemy. It is conceded that, without remarkably successful civic training in self-restraint, the police and the courts, to say nothing of the ordinary citizen, may be unable to tolerate dissent in the midst of crisis.

Experience gained in attempting to understand and in some measure to guide the evolution of modernizing states has drawn renewed attention to the preconditions of a body politic wherein a free forum is protected by lawful coercion. The timing of transitional policies in such a state seems to require that the advantages

when totalitarian states institute and maintain strict censorship and total propaganda. The purpose on the one hand is to insulate the home audience from outside influences, and on the other to obtain maximum access to nontotalitarian audiences.

The very presence of propaganda raises searching problems for the friend of freedom. Does the calculated manipulation of attitudes imply a denial of respect for freedom of opinion? This is true if the forum of communication is not equally accessible to all and if educational opportunities are open only to the privileged. Hence, in countries that aspire toward freedom, stress is laid upon measures designed to achieve genuine equality. Responsible news media and the legislative and judicial institutions of society proceed by the use of discussion and debate in order to subject rival propaganda claims to a common discipline of balanced presentation and of critical evaluation of evidence. Whatever solutions of the control of communication are achieved, the degree of protection received by unpopular opinion and propaganda will continue to be one of the chief working tests of freedom.

PROPANE, a colourless, gaseous compound of carbon and hydrogen, the third member of the paraffin series following methane and ethane. The formula for propane is C_3H_8 . It is separated in large quantities from natural gas, light crude oil and oil refinery gases and is commercially available as liquefied propane or as a major constituent of liquefied petroleum gas (LPG).

As with ethane (*q.v.*) and other paraffin hydrocarbons, propane is an important raw material for the ethylene petrochemical industry. The decomposition of propane in hot tubes to form ethylene also yields another important product, propylene. From propylene organic chemicals like acetone, propylene glycol and many others are derived. The oxidation of propane to such compounds of carbon, hydrogen and oxygen as acetaldehyde is also of commercial interest.

Although a gas at ordinary atmospheric pressure, propane is readily liquefied under elevated pressures. It is therefore transported and handled as a liquid in cylinders or tanks. In this form, alone or mixed with liquid butane, it has great importance as a fuel for domestic and industrial uses and for internal-combustion engines.

In the mid-20th century, world reserves were estimated at about 10,000,000,000 tons. The annual production was about 0.2% of this figure. Consumption was about equally distributed among chemical uses, LPG and as an unseparated constituent in natural gas used as fuel. (F. B. B.)

PROPELLANTS, chemical compounds or mixtures of compounds used to: (1) propel rockets or missiles or (2) propel projectiles through the tubes of guns, howitzers, mortars or other firearms. Their propelling force results from rapid burning and evolution of hot gases that exert a sustained forward force or pressure on the missile or projectile. One important feature of a propellant is that it supplies its own oxygen, whereas fuels such as coal and gasoline must obtain oxygen from the air. This feature is essential for missiles to continue accelerating as they reach outer space.

SOLID PROPELLANTS

History.—Gunpowder, or black powder, was the original propellant that used controlled explosive forces. This material may have been known much earlier than the 14th century and may have been used in various rockets and other mysterious fire-producing devices, but the evidence is not conclusive. For more than 550 years, with some variation in composition and physical form, gun-

of forsaking the old and adopting the new be prompt and visible. Since propaganda is an instrument of visibility and anticipation it can be effectively used under these circumstances if there is presentation of costs as well as gains, and of risks as well as promises.

The appropriate role of propaganda is becoming more problematic in advanced industrial societies. To an increasing degree the leaders of thought and action in such societies are disturbed by evidence of inner demoralization that cuts across the ideological cleavages of a world permeated by the expectation of violence. The problem is often called the alienation of many members of the younger generations; dissociated from society, they refuse to accept civic responsibility. The question is whether propagandas of "official indoctrination," at one extreme, or of "competitive distraction and anarchy," at the other, can be effectively harmonized with the realities of life in industrial societies in ways that will deter or prevent juvenile crime or self-destructive fads. The "postponement of maturity," which exaggerates the seeming powerlessness and superfluousness of the young, may generate subterranean predispositions and propaganda initiatives that undermine the established order.

To the traditional importance of providing institutional arrangements for the protection of unpopular opinion it may be necessary to add, as an objective of policy, cultivation of incentives for the young to have opinions on any kind of public policy.

One of the greatest dangers arising from the prevalence of propaganda in a free society is that the vigorous prosecution of special interests may prevent the formation of a genuine public will. In times of crisis this may put democratic countries at a disadvantage

powder adequately served man in the full range of firearms, both military and sporting. (See GUNPOWDER.)

But gunpowder had recognized deficiencies. Because it was a mechanical mixture of carbon, sulfur and potassium nitrate or sodium nitrate, its composition and properties were bound to vary. Gunpowder was also far from clean burning, it left troublesome residues in guns and produced large clouds of smoke and usually bright muzzle flashes. Other problems were caused by the tendency of some of the ingredients, notably the nitrate, to absorb moisture; there were also serious hazards in the manufacture of gunpowder.

The successor to gunpowder as a propellant was a substance called smokeless powder, the term smokeless reflecting the cleaner burning of the nitrocellulose propellant as compared with gunpowder. Guncotton, the earliest known form of nitrocellulose, was first described in 1846 by the Swiss-German chemist C. F. Schönbein, who experimented with its explosive nature and suggested its use in firearms. In modern terminology, guncotton means nitrocellulose with a nitrogen content of 13% or more. The term more common than guncotton is high-grade nitrocellulose.

The first attempts to utilize nitrocellulose as a propellant were unsuccessful, some actually disastrous, for two main reasons: (1) the material was chemically unstable, because of the reactions of the residual acid in the fibres, and (2) the raw fibrous nitrocellulose presented an excessive burning area to the flame front. Later the stability problem was solved by a more complete removal of the residual acid from the nitrocellulose fibres and by an addition of chemical stabilizers such as diphenylamine.

Schönbein is also credited with being the first to treat nitrocellulose with alcohol and ether to form collodion (*q.v.*). However, it remained for Paul Vieille (1854-1934), a French physicist and chemist, to utilize this colliding action of solvents in molding the now homogeneous mass into shapes of controlled dimensions and surface areas. This was an extremely important discovery because it laid the groundwork for successful development of colloidal nitrocellulose propellants with improved and controllable ballistic characteristics. The French army adopted the new and more powerful propellant about 1885 as poudre B.

The next step in propellant development occurred in 1888 when Alfred B. Nobel (*q.v.*), a Swedish chemist and engineer, discovered the solvent and colliding actions of nitroglycerin on nitrocellulose and combined them into a more powerful propellant termed ballistite. As it contained both nitroglycerin and nitrocellulose, it was described as a double-base propellant.

In 1890 Sir Frederick A. Abel, a British chemist, invented cordite, another double-base propellant consisting of 65% nitrocellulose, 30% nitroglycerin and 5% mineral jelly. Cordite was made by extruding the colloid into long cords, whereas both Vieille and Nobel had rolled the colloid into sheets and then cut the sheets into flakes of various sizes. Before the end of the 19th century, the U.S. navy adopted smokeless powder, favouring the single-base type of Vieille and using nitrocellulose of approximately 12.6% nitrogen—it was often called pyrocellulose, or simply pyro.

Early 20th Century.—These two general types, single-base and double-base, served almost exclusively as standard propellants for military and civilian use during the early 20th century. Even when the rocket or jet-propelled type of weapon came into military use, the double-base propellant, still termed ballistite, found extensive application.

After World War I, important refinements were made in U.S. army single-base propellants. For example, the ingredients dinitrotoluene and dibutylphthalate were added to the nitrocellulose, effectively moisture-proofing the propellant grains. Ingredients in this improved propellant were also proportioned to eliminate muzzle flash when fired from the French 75 mm. gun which was extensively used by the Allied armies. The new propellant was known as flashless-nonhygroscopic (FNH) or more officially as duPont FNH-M1 in recognition of the co-operative developmental efforts of E. I. duPont de Nemours and company. Later it was designated as propellant M1, and a slight variation for the larger guns as propellant M6. Table I shows the nominal formulas and two calculated properties of these important U.S. propellants.

TABLE I.—Data on M1 and M6 Propellants

Ingredients	M1	M6
Nitrocellulose (13.15%) N	85	87
Dinitrotoluene	10	10
Dibutylphthalate	5	3
Diphenylamine*	1	1
Isochoric flame temperatures (°K)	2417	2570
Ballistic force (ft.lb./lb.×10 ⁻³)	305	317

*Diphenylamine is added and serves as a chemical stabilizer for the nitrocellulose.

World War II Era.—During World War II a number of important developments affected the military propellant field. A more nearly flashless gun propellant (cordite N) was introduced in England. Rockets and jet-propelled missiles gained in importance of the first magnitude. Large rockets, in turn, brought into prominence another type of solid propellant, termed composite, as well as liquid propellants.

Cordite N was a triple-base type that contained a third explosive compound, nitroguanidine, in an amount of approximately 55%. This compound was also used by Germany and perhaps other countries, but usually with somewhat smaller percentages of nitroguanidine. The high nitrogen content (55%) in nitroguanidine imparts a special cool-burning property to the propellant, thus aiding in flash control and reducing erosion rates. Addition of salts such as potassium sulfate (K₂SO₄) in small percentages (cordite N/P) further increased the flashless properties of this type of propellant, though even 1% of K₂SO₄ greatly multiplied the amount of smoke produced.

Cordite N propellant was adopted in the early 1940s for many guns in the United Kingdom services and in Canada, and by the U.S. navy even for its largest guns. The U.S. army adopted a slight modification of cordite N as the M15, carefully designed for optimum flashless-smokeless performance where this double feature had special importance, as in tank guns. The U.S. army also adopted a further modification as the M17, designed especially to impart maximum muzzle energy to solid armour-piercing types of projectiles. Typical nominal formulas and important characteristics of these three triple-base propellants are shown in Table II.

These values of flame temperature and force represent about the normal range for military gun propellants. Double-base types for mortars, rockets and recoilless rifles have considerably higher flame temperatures.

Small Arms.—The earliest small arms propellant was gun-

*Diethyl diphenyl urea.

powder and many a vivid picture comes to mind of the western U.S. pioneer tamping the powder charge and the bullet into his muzzle-loader. The earliest colloidal propellant was probably made in the form of flakes but later more progressive burning, and therefore greater efficiency, was secured by using an extruded grain with a single perforation and by applying a deterrent coating to the outside of the grains. This design was standard for almost all types of military rifles and culminated in the development of the well-known IMR (Improved Military Rifle) propellant by the duPont company. The IMR propellants and most other small-arms propellants were of the single-base type, although some double-base types were used in pistols and shotguns.

In the United States the non-military use of small-arms propellants has always been considerable; this was especially true during the early periods when game was plentiful and was a significant item of food. More recently the small-arms ammunition market has been expanding in the area of sporting contests and target practice.

An important propellant development was made by the Western Cartridge company (later a division of the Olin-Mathieson Chemical corporation) in the 1930s. The propellant was called Western ball powder. The production technique was to dissolve or disperse the nitrocellulose and other ingredients in a solvent such as ethyl acetate. Upon agitation and the addition of a protective colloid, the lacquer was broken up into small spherical globules. The process provided an effective means of purifying the nitrocellulose and also lent itself well to making either single-base or double-base propellants. The particular design submitted for military use in small-arms weapons showed a significant improvement in the form of longer barrel life for the weapons. The novel spherical form and design of the propellant grain may have contributed to this fortunate result. However, the relatively low flame temperature of the particular composition in use in those specific tests appears to have been the most significant factor. See also SMALL ARMS, MILITARY.

Rockets and Missiles.—As noted earlier, the double-base ballistite type was the popular solid propellant used in rockets of small and some medium sizes—notably the bazooka (*q.v.*). As made by the extrusion process, ballistite had definite limitations as to diameter of strand. Therefore, as missile sizes increased, various casting and pressing processes had to be devised to fabricate larger sizes of propellant grains required by the motors. Various complex shapes of grain were also needed to produce the desired burning characteristics. (The word grain is still used to designate discrete particles regardless of size.)

The casting and other methods of fabrication opened the way for the composite type of propellant for missiles and JATO's (jet-assisted take-off devices) with an almost unlimited range of sizes and capabilities. In these heterogeneous mixtures of chemical compounds there may be fuels, either organic or metallic; oxidizers (nitrates, perchlorates, etc.); binders and other special-purpose ingredients such as burning-rate controllers or accelerating additives.

The composite type of propellant provides for considerable flexibility in design and in the variety of fabrication methods. Solid-propellant grains may be cast with liquid nitroesters or other compounds filling the voids, thus providing the typical heterogeneous mass with evenly distributed components. The casting or pressing may be done in a special mold or an inert plastic container which later acts as an inhibitor and thus restricts burning to the end of the composite mass. Or the entire charge may be cast or pressed into the missile motor itself, the walls of which automatically provide an inhibiting action.

To develop a solid propellant for a given purpose, skilful design and careful manufacturing control are essential for each

specific application because of the many severe performance requirements and limitations placed upon modern propellants. In addition, most propellants, especially in military use, must be stable chemically and ballistically for safe storage over long periods of time. The chemical compounds must include only such ingredients as are compatible or nonreactive until actual functioning is desired.

Certain stabilizing compounds such as diphenylamine may be needed to neutralize the effects of the possible slow hydrolysis of nitrocellulose or other nitrates.

LIQUID PROPELLANTS

Although solid propellants have been the workhorses for many centuries, liquids have gained distinctive roles in modern missile technology. The experiments of Robert H. Goddard (*q.v.*) in the 1920s charted the course; he visualized a system using liquid hydrogen and liquid oxygen as being capable of energizing even an interplanetary rocket. The German V-2 missile of World War II was a milestone in actual application of two liquids, alcohol and liquid oxygen (LOX).

Liquid systems are of two types: monopropellants and bipropellants. A monopropellant may be a single compound such as ethyl nitrate, or it may be a compatible mixture such as hydrazine, hydrazine nitrate and water. Bipropellants consist of two liquids, one an oxidizer and the other a fuel; they are kept separate until they reach the combustion chamber. Most bipropellants ignite spontaneously on contact and are therefore said to be hypergolic. Typical oxidizers are liquid oxygen, fuming nitric acid and hydrogen peroxide; fuels include aniline, hydrazine and alcohol. Monopropellants are usually chosen for the few gun applications of liquids; most liquid-missile systems use bipropellants because of their greater energy capabilities.

The choice between liquid propellants and solid propellants for a given missile often depends upon the nature and severity of the launching and flight requirements and on the limitations of the missile system itself. In practice the larger missiles may utilize two or more stages, with liquid and solid propellants in different stages of the same missile. Each stage consists of a separate motor that may be discarded after propellant burnout is complete.

Another important factor is the time period required for operational stability. Many solid propellants remain essentially unchanged for years, whereas the high energy of liquid oxygen is available for a very short time unless elaborate refrigeration is provided. Practical considerations include tactical convenience and safety in supply, transportation, handling and storage. Solid propellants are easy to handle and may be kept for long periods in a ready-to-fire status; liquid propellants offer higher specific impulse but at the cost of many tactical problems.

Perhaps the two most fundamental properties of many propellants, at least solids, are that their functioning is essentially a surface-burning phenomenon and that the burning rate at any instant depends upon the pressure existing in the surrounding gaseous medium. Thus, Vieille in 1888 showed that the burning rate r is proportional to the pressure P : $r = c P^n$, where c is a constant characteristic of the chemical composition and n is essentially constant, usually in the range 0.8 to 1.0. Surface burning (rather than detonation of the mass, as in explosives like TNT) is utilized to guide the reaction toward maximum efficiency. Thus the pressure may be sustained by designing the solid-propellant grain so that the

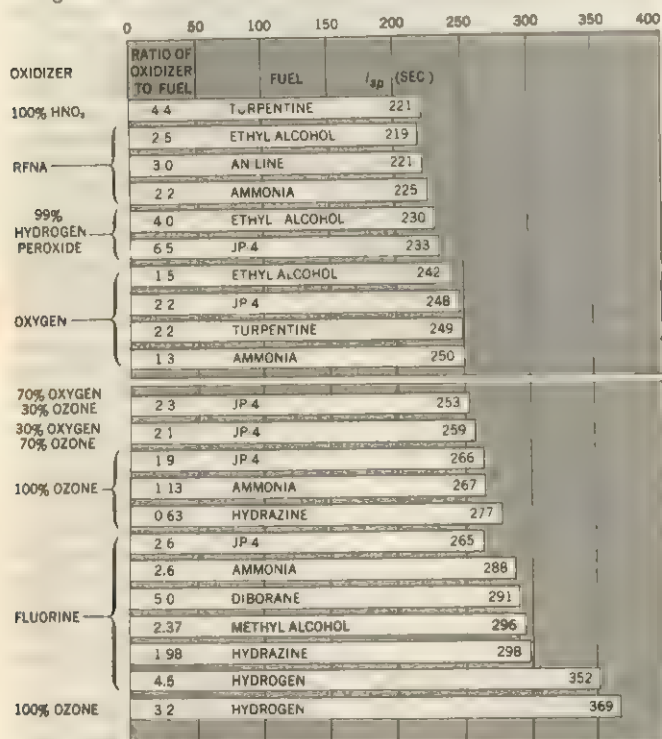

FIG. 1.—SOLID-PROPELLANT GRAIN CONFIGURATIONS

area exposed to the flame front remains constant, or may even increase as burning proceeds. This is done by varying the geometry of the grain (see fig. 1) or by using inert deterrent materials on grain surfaces. The value of c in Vieille's law may be altered materially in modern practice by incorporating selected high-energy fuels (as magnesium or aluminum), by rate control strands, by using additives with a high-burning rate and by incorporating special ingredients that broaden the pressure-time curve and thus increase the total-thrust energy imparted to the missile.

For long-range missiles the urgent demand is for the maximum possible power or sustained thrust. The fundamental measure for power of a given propellant is specific impulse (abbreviated I_{sp}). In the simplest form $I_{sp} = F/W$ sec., where W is the average rate of propellant consumption in pounds per second, to produce the average total thrust F in pounds. This relationship shows the value of high-energy compounds, capable of producing high values of F ; and of chemicals with low molecular weight, thus lowering the value of W . In these relationships liquid compounds show great potential gains over solids because of the variety of fuels containing hydrogen and of such high-energy oxidizers as liquid oxygen, fluorine and ozone.

Fig. 2 indicates the broad possibilities for specific impulse, but

FROM "CHEMICAL AND ENGINEERING NEWS," VOL. 38, NO. 21, P. 20 (1957)

FIG. 2.—THEORETICAL SPECIFIC IMPULSE (I_{sp}) FOR LIQUID-PROPELLANT COMBINATIONS

of course the practicability of using these high-energy combinations depends upon many other factors. By way of comparison, double-base solid propellants develop a specific impulse of about 230 sec., composites do somewhat better, in the order of 250 to 290 sec. These values for I_{sp} should be contrasted with the fig. 2 levels of up to 369 for high-energy liquid systems. Such values of I_{sp} may well be approaching the upper limit attainable by combinations of conventional chemical compounds. Further increases into ultraenergy regions may depend upon success in harnessing free radicals and atomic energy sources. See also AMMUNITION, ARTILLERY; ROCKETS AND GUIDED MISSILES.

PROPERTIUS, SEXTUS (c. 50-c. 15 B.C.), the greatest of the elegiac poets of Rome, was born of a well-to-do Umbrian family at or near Asisium (Assisi). Ovid says that Propertius was his senior, but also his friend and companion; and that he was third in the sequence of elegiac poets, following Cornelius Gallus who was born c. 70 B.C., and Tibullus, and immediately preceding Ovid himself, who was born in 43 B.C. It may be supposed then that he was born c. 50 B.C.

His early life was full of misfortune. He lost his father prematurely; and after the battle of Philippi and the return of Octavian to Rome, Propertius, like Virgil and Horace, was deprived of his estate to provide land for the veterans, but, unlike them, had no patrons at court and was reduced from opulence to comparative indigence. When the widespread expropriations had provoked an insurrection, Propertius lost another of his relatives, who was killed by brigands while making his escape from Perugia (Perugia), the centre of the revolt. The loss of his patrimony, however, did not prevent Propertius from receiving a superior education, thanks no doubt to his mother's providence. Eventually he and she left Umbria for Rome; and there, c. 34 B.C., he assumed the dress of adult manhood.

Propertius was urged to take up a pleader's profession; but, like Ovid, he found in letters and gallantry a more congenial pursuit. Soon afterward he made the acquaintance of Lycinna (about whom little is known beyond the fact that she subsequently excited the jealousy of her successor, Cynthia) and was subjected to all her powers of persecution (*vexandi*). This passing fancy was succeeded by a serious attachment, the object of which was the famous "Cynthia." Her real name was Hostia (according to Apuleius, *Apologia*, 10); and she was a courtesan of the superior class, somewhat older than Propertius and, it seems, of singular beauty and varied accomplishments. Her own predilections led her to literature; and in her society Propertius found the intellectual sympathy and encouragement which were essential for the development of his talent. Her character, as depicted in the poems, is not an attractive one; but she seems to have entertained a genuine affection for her lover. Their intimacy lasted from c. 29 to 24 B.C. These years must not, however, be supposed to have been a period of unbroken felicity. Apart from minor disagreements an infidelity on Propertius's part excited the deepest resentment in Cynthia; and at some time he was banished from her society for a year. When he had known Cynthia for about a year Propertius published his first book of poems, which was inscribed with her name. Its publication placed him in the first rank of contemporary poets and procured him admission to the literary circle of Maecenas. The subsequent relationship between the poet and his mistress, however, was one of growing disenchantment; neither was faithful to the other; the mutual ardour gradually cooled; motives of prudence and decorum urged the discontinuance of the connection; and disillusion changed insensibly to disgust.

Although their parting might have been expected to be final, it is not certain that it was so. Though Cynthia, whose health appears to have been weak, does not seem to have survived the separation long, the poem (iv, 7) in which Propertius describes a dream of her that he had after her death suggests that they were once more reconciled and that in her last illness Cynthia left to him the duty of carrying out her wishes with regard to the disposal of her effects and her funeral. Almost nothing is known of the subsequent life of the poet. He was alive in 16 B.C., as some allusions in his last book show. Moreover, two passages in the letters of the younger Pliny mention a descendant of the poet, one Passennus Paulus; and this had given rise to the suggestion that Propertius may have married in order to comply promptly with the *leges Juliae* of 18 B.C. (which offered inducements to

marriage and imposed disabilities upon the celibate) and had at least one child.

Propertius had a large number of friends and acquaintances, chiefly literary men belonging to the circle of Maecenas. Among them may be mentioned Virgil, an epic poet called Ponticus, a certain Bassus (probably the iambic poet) and at a later period Ovid. He says nothing of Tibullus or of Horace, who also never mentions Propertius. This reciprocal silence may be significant.

In person Propertius was pale and thin, as was to be expected in one of a delicate and even sickly constitution. He was very careful about his personal appearance and paid an almost foppish attention to dress and gait. He was of a somewhat voluptuous and self-indulgent temperament, which shrank from danger and active exertion. He was anxiously sensitive about the opinion of others, eager for their sympathy and regard and, in general, easily influenced by them. His over-emotional nature passed rapidly from one phase of feeling to another; but the more melancholy moods predominated. A vein of sadness runs through his poems, sometimes breaking out into querulous exclamation, but more frequently expressed in gloomy reflections and prognostications. He had fits of superstition, which in healthier moments he despised.

The Poems.—The poems of Propertius, as they have been preserved, consist of four books containing just more than 4,000 lines of elegiac verse. Book i, the *Cynthia* or *Monobiblos*, was published probably in 29 or 28 B.C. As its title indicates, it is concerned almost exclusively with the poet's passion for Cynthia. The arrangement of the poems is, in the Alexandrian manner, one of artful disorder: the phases of the liaison and of Propertius's feelings are described in a series of brilliant isolated impressions, in which a strict chronology is carefully avoided (compare Ovid's *Amores*). This is not the only reason why it is unsafe to draw inferences about Propertius's actual life and loves from his poetry. Throughout, but particularly in the first book, reality and convention, experience and literary artifice, love and learning, are too intimately blended for the reader to be sure of disentangling them. It is important to remember the poet's essentially urban character and the relatively small and highly sophisticated circle of readers to whom his poetry was intended to appeal: for them his mythological allusions, which are frigid and indeed barely intelligible to the modern reader, would be immediately moving and evocative. Books ii and iii, which were published probably c. 25 and c. 22 B.C. respectively, are of somewhat more varied composition than book i. The poet's love for Cynthia still dominates them, but his tone is more declamatory and less personal, and other themes are heard.

Book iv (c. 16 B.C.) offers a remarkable contrast. Propertius had indeed already announced, at the beginning of book iii, that he aspired to follow in the footsteps of Callimachus and Philetas, but there he had been referring only to formal and stylistic obligations, not to subject matter; whereas now (iv. 1. 61–70) he proposed, as the Roman Callimachus, to deal with the history and antiquities of Rome in the manner of the *Aetia*. In fact such themes, which were taken up later by Ovid in the *Fasti*, only occupy five of the poems in the book. The rest, a varied collection, include the poem (3) which seems to have given Ovid the idea for his *Heroides*; a delightfully humorous description of Cynthia's surprising Propertius in the act of being unfaithful to her (8); and the eulogy of the dead Cornelia, which some have thought to be his finest work (11).

The writings of Propertius are noted for their difficulty and their disorder. The workmanship is unequal, curtness alternating with redundancy, and carelessness with elaboration. A desultory sequence of ideas, an excessive vagueness and indirectness of expression, a peculiar and abnormal latinity, a constant tendency to exaggeration and an immoderate indulgence in learned and literary allusions—all these are obstacles lying in the way of a study of Propertius. But those who surmount them will find their trouble well repaid. For power and range of imagination, for freshness and vividness of conception, for truth and originality of presentation, few Roman poets can compare with him when he is at his best; that is, when he is carried out of himself, when the discordant qualities of his genius are, so to say, fused together

by the spark of immediate inspiration. His vanity and egotism are redeemed by his fancy and his humour.

Two of the lasting merits of Propertius seem to have impressed the ancients themselves. The first they called *blanditia*, a vague but expressive word by which they meant softness of outline, warmth of colouring, a fine and almost voluptuous feeling for beauty of every kind and a pleading and melancholy tenderness; this is most obvious in his descriptive passages and in his portrayal of emotion. His second and even more remarkable quality is poetic *facundia*, or command of striking and appropriate language. Not only is his vocabulary extensive but his employment of it is extraordinarily bold and unconventional: poetic and colloquial latinity alternate abruptly, and in his quest for the striking expression he frequently seems to strain the language to breaking point.

Propertius's handling of the elegiac couplet, and particularly of its second line, deserves especial recognition. It is vigorous, varied and even picturesque. In the matter of the rhythms, caesuras and elisions which it allows, the metrical treatment is much more severe than that of Catullus, but noticeably freer than that of Ovid, to whose stricter usage, however, Propertius increasingly tended (particularly in his preference for a disyllabic word at the end of the pentameter). An elaborate symmetry is observable in the construction of many of his elegies, and this has tempted critics to divide a number of them into strophes.

Influence.—As Propertius had borrowed from his predecessors, so his successors, Ovid above all, borrowed from him; and *graffiti* on the walls of Pompeii attest his popularity in the 1st century A.D. In the middle ages he was virtually forgotten; and since the Renaissance he has been studied by professional scholars more than he has been enjoyed by the general public. To the modern reader, acquainted with the psychological discoveries of the 20th century, the self-revelations of his passionate, fitful, brooding spirit are of peculiar interest.

BIBLIOGRAPHY.—For the text of the poems see the editions by E. A. Barber (1953) and by M. Schuster, 2nd ed. rev. by F. Dornseiff (1958). For the text with introduction and commentary see the edition by H. E. Butler and E. A. Barber (1933); also that of book i only by P. J. Enk, with bibliography (1946). There are English translations in prose by H. E. Butler, with the Latin, in the "Loeb Series" (1912); and in verse by S. G. Treemenheere, 2nd ed. (1932), and by E. H. W. Meyerstein, with bibliography (1935). See further F. Plessis, *Études critiques sur Propertius et ses élégies* (1884); W. Y. Sellar, *Horace and the Elegiac Poets* (1899); R. Helm, "Propertius," in Pauly-Wissowa, *Real-Encyclopädie*, vol. xxiii (1957). (J. P. P.; E. J. Kv.)

PROPERTY, a term used popularly to refer to a thing owned by a person, but used more accurately in law to refer to a scheme of relationships, recognized or established by government, between individuals with respect to an object. The object may be tangible, such as land, or completely the creature of law, such as a patent or copyright. Since the objects of property and the protected relationships vary among societies and over time, it is difficult to find a least common denominator of property. "My property" probably means at a minimum that government will help me exclude others from the use or enjoyment of an object without my consent, which I may withhold except at a price. Legal relationships with respect to objects are described in the following articles: **REAL PROPERTY** and **CONVEYANCING, LAWS OF; PERSONAL PROPERTY; LANDLORD AND TENANT; COMMERCIAL PAPER; COPYRIGHT; and PATENT**. See also references under "Property" in the Index.

(A. Dm.)

PROPHET, a Greek word (*prophetes*) denoting one who conveys a divine utterance and thus serves as the "mouthpiece" of a god (cf. also Ex. 7:1 and 4:16). In classical Greek the term could signify either the person uttering the oracle (*q.v.*) or (since the utterance would often be unintelligible) the one interpreting it, in which case a distinction would be made between *mantis* (also translated "prophet") and *prophetes*. The Greek version of the Old Testament uses the word *prophetes* to render the Hebrew *nabi* (see below, *Israelite Prophecy*), and from there the words prophet, prophecy, prophetic, etc. entered other European languages. Since the prophet's utterance often foretold the future—to warn, to announce the inevitable, or in reply to clients consulting the oracle—prophecy has at times been equated with prediction (see **DIVINA**—

tion). Nevertheless, it has rightly been remarked that prophecy is a matter of "telling forth" rather than "foretelling," although the latter may at times be the more prominent feature.

THE PROPHETIC PHENOMENON

Any attempt at an adequate description of the prophetic phenomenon is brought up against a serious methodological dilemma: The analysis will either refer to one particular culture only, in which case it may be exhaustive but include unessential detail; or else it will embrace many cultures and run the risk of treating the subject in too generalizing a fashion. As a matter of historical fact, the most outstanding and influential prophetic phenomenon, as far as Western culture is concerned, was Israelite prophecy, and most students of the subject have necessarily drawn on the biblical material. Hence some overlap between a general phenomenology of prophecy and the specific analysis of Hebrew prophecy is all but inevitable. However, it is generally agreed that similar phenomena in other cultures and religions, though known by different names and performing somewhat different social functions, may legitimately be discussed under the one heading.

Sources of Prophecy and the Prophetic State.—The prophet differs from other religious functionaries and representatives of religious authority in that he claims no personal part in his utterance. He speaks not his own mind but a revelation "from without." He may be "inspired" with his message (as in Jer. 1:9, "Behold, I have put my words in your mouth") or he may be "possessed" by a spiritual power—a god, a spirit, the Holy Ghost—which uses him as an instrument and speaks through him (as in Aeschylus' description of Cassandra in the *Agamemnon* and of the prophet of Apollo in the *Eumenides*). Plato (*Timaeus* 71b) defined the prophet as one who speaks in ecstasy, and in the Hellenistic period Philo of Alexandria similarly stated that the prophet "speaks nothing of his own" but resembles the lyre on which someone else plays.

Prophecy is, therefore, a "pneumatic" (under the influence of the "spirit") and "enthusiastic" state, ranging from controlled possession or a certain "infused" heightening of natural powers to frenzied ecstasy, convulsive seizures, or catalepsy amounting to a temporary loss of personality. Saul, when the spirit came upon him, was "turned into another man" (I Sam. 10:6), and "he too stripped off his clothes, and he too prophesied before Samuel, and lay naked all that day and all that night" (19:24). The prophetic state may occur spontaneously or it may be induced by a variety of techniques: by meditation, by mystico-magical formulas and gestures (the *mantras* and *mudras* of esoteric Buddhism, for example), by music (II Kings 3:15, "And when the minstrel played, the power of the Lord came upon him"), by drumming, dancing, or the ingestion of intoxicants or narcotics. Prophets very often resist the call (Amos and Jeremiah among the Hebrew prophets; many prospective shamans) until overcome by the superior power that wants to use them as its instrument.

The resultant charismatic (from *charisma*, a divine gift) possession may express itself in acts of physical prowess, as in the case of the Israelite judges (Samson, for example); in (magical) powers of diverse kinds, as the curing in shamanism (*q.v.*); or in inspired speech. The latter may be unintelligible gibberish (*see* TONGUES, GIFT OF), a foreign tongue, or even pseudo-language (*xenoglossia*), or it may be clear and meaningful speech, uttered in an elevated style and rhythmic diction. It is the intelligible utterance to which the term prophecy is applied more specifically (*cf.* I Cor. 14:29-32). The prophetic state may be accompanied by visions, auditions, and other experiences, as well as by total loss of consciousness.

Prophets and Other Diviners.—Using the criterion of inspired speech, it becomes possible to distinguish the prophet from related types of religious functionaries. Although the prophet often acts as a diviner, he is largely dependent on an outside power, which in some cultures he has at his disposal but in others may not always control. Nonprophetic divination uses or manipulates objective techniques or signs; *e.g.*, the ephod, and the Urim and Thummim of the Israelite priests; the spirits of the dead consulted

in necromancy; the animal livers studied by the divining hepatoscopes in Babylonia and elsewhere; the flight of birds observed by the Roman augurs; the animal entrails examined by the Etruscan haruspices. The diviner is consulted by clients, whereas the prophet, impelled by the spirit, may also go out and thrust his message on an unwilling audience. Both prophets and diviners, like priests, are mediators between the ordinary man and the divine powers. The word *kahin*, which in ancient Arabia meant an inspired soothsayer, is derived from the same Semitic root as Hebrew *kohen*, "priest."

Frequently both divination and prophecy are connected with a sanctuary and practised by priestly or semipriestly guilds, or at least are organized or controlled by the priesthood. On the other hand the prophet may be moved to oppose the priestly establishment. But the opposition priest-prophet has, in fact, been somewhat overstressed by some scholars. Even Amos, while emphatically denying any association with prophetic groups (Amos 7:14), uttered his prophecy at the sanctuary of Bethel (7:12-13), the "temple of the kingdom." Divination, like magic, though frequently serving social and collective ends—decisions regarding wars or hunting expeditions, rainmaking, etc.—is more often concerned with private needs and anxieties. In either case it deals with very specific and limited problems. The prophet, impelled by the spirit, may articulate a message of more general and fundamental import, and enunciate principles and norms that are critical of the present, in either a destructive or a reforming sense. He may address his group (tribe, nation) as a whole or may found a new society which will realize his message. The prophetic personality thus frequently becomes a religious founder, reformer, or sectarian leader (Zoroaster, Muhammad, and others). The "ideal-typical" prophet (in Max Weber's sense) is, however, less concerned with founding a new religion or introducing revolutionary reforms than with criticizing his society from the inside, as it were, and in the light of what he believes to be the divinely established norms underlying its existence. If he is a revolutionary he very frequently does not know it.

The Prophetic Message and Prophetic Religion.—The above characterization has drawn heavily on the classical pattern of apostolic prophecy as exhibited by the Hebrew prophets. It is called apostolic because the prophet—unlike the priest who presides over the ritual, or the teacher who expounds doctrine, or the saintly or ascetic "exemplary" leaders—delivers a message. Discussions of the nature of prophecy therefore vary according to whether they emphasize its formal elements (possession, inspiration, sense of vocation and mission) or the contents of the message (righteousness, purity of heart, universal peace, divine judgment, etc.).

The semantic spectrum of the term prophetic has consequently become rather wide. According to whether the emphasis is on possession and ecstasy, inspired utterance, prediction of the future, visionary experience, ethical fervour, passionate social criticism, sense of absolute commitment, millenarian and apocalyptic expectation, etc., the most diverse phenomena and personalities have been called prophetic: Montanists, Pentecostals, Zoroaster, Muhammad, Joachim of Fiore, Savonarola, Thomas Müntzer, Jakob Böhme, George Fox, Joseph Smith, and many others. The moral seriousness of the ancient Chinese sages and their profound regard for the law of heaven has suggested comparisons with Hebrew prophecy, and the Egyptian text known as the "Peasant's Complaint" has been claimed as a witness for a prophetic movement in ancient Egypt. Even Marxism has at times been qualified as prophetic, both because of its passionate protest against social injustice and because of the eschatological structure of its doctrine.

Disregarding, for our present purpose, this wide and at times merely figurative use of "prophetic," there is little doubt that a distinct prophetic type of religion can be recognized. Its main characteristics are a dynamic conception of the Deity, an emphasis on the will (both of God and of man) as a constitutive of the religious reality, a basic dualism (qualitative gulf between God and man, yet personal and even "dialogical" relationship in faith and obedience), a profound awareness of the seriousness of sin (as dis-

tinct from breaking a taboo), a radical ethical outlook based on an unequivocal choice between good and evil, a positive attitude to society and to this world in general, and a relationship to the time process which could crystallize in eschatological and messianic hopes. (R. J. Z. W.)

PROPHECY IN WORLD RELIGION

ANCIENT NEAR EAST

Prophets were to be found throughout most of the ancient Near Eastern world. Though their activities varied considerably from culture to culture, certain common features are discernible. Because much of their labour centred on advising with regard to future events, the prophets functioned as one kind of diviners at the side of specialists in other divinatory techniques. Inasmuch as the inspired delivery of oracles was part of the rituals of the ancient world, particularly on the occasion of great festivals, prophets were often connected with the temples as regular cultic officials. Prophets also accompanied the kings in battle, giving guidance from the gods.

Some texts suggest that prophets had the freedom to bring their oracles to king and people without having been asked to do so and even if their message expressed criticism of the monarch. Rare though such examples be, they foreshadow the later developments of Israelite prophecy.

Ecstatic prophecy seems to have been rare in Egypt, perhaps because the kings were themselves held to be gods incarnate and hence in a position to provide divine counsel in their own right.

ISRAELITE PROPHECY

The Hebrew noun *nabi* ("prophet," pl. *nabi'im*) is probably related etymologically to the Akkadian verb *nabû* ("to call," "to name"). If this derivation is correct, it would suggest either that the prophet was understood as "the one called out" (by the deity, to speak in his name) or that he was understood to be "the caller" (i.e., the spokesman for the deity). Judgments differ as to whether *nabi* should be taken to be a passive or an active form of the noun. Many other etymologies and meanings for the term have also been proposed. The term for prophet in early Israel was, according to I Sam. 9:9, *Ro'eh*, "seer." Another popular designation for the prophet was *hoseh*, "visionary" (Amos 7:12; Isa. 30:10; translated "seer" or "prophet" in English Bibles).

But the origins of what is distinctive of the prophetic tradition in Israel are not traceable by reference to the occurrence of the various names given the prophets. Israelite prophecy is fundamentally rooted in the covenant (*q.v.*) faith of early Israel, which, according to Old Testament tradition, is inseparably connected with the experiences and the work of Moses. Moses is considered by later tradition to be the greatest of the prophets (*e.g.*, Num. 11:29; Deut. 34:10). Events in the life of early Israel and the community's understanding of these events have prepared the soil in which Israelite prophecy is to grow and flourish. The understanding of God as sovereign Lord, redeemer of the oppressed slaves, guide and helper in time of danger, jealous of his prerogatives and demanding unswerving allegiance, engaged in a purpose which includes "all the families of the earth" (Gen. 12:3)—this understanding of the nature and work of God gives the setting and the distinctive stamp to Israelite prophecy.

Origins of the Office of Prophet.—Prophets as a distinct class within Israelite society first appear in the days of Samuel and Saul. During the latter half of the 11th century B.C., bands of prophets were found in several Israelite localities (Gibeah, Ramah); Samuel and Saul were very closely related to them (I Sam. 10:1; 19:18-24). The significance of the ecstatic prophets is not made clear in the texts which speak of them, perhaps because the later Israelite tradition did not wish to associate them too closely with the classical prophets. Yet the movement must have provided much of the impetus which led the Israelite tribes to rally in defense of their land against the Philistines.

These uncontrolled and uncontrollable spokesmen for the God of Israel apparently occupied an ambiguous position within the community. The question "Is Saul also among the prophets?" (I Sam. 10:12; 19:24), and the designation of the prophetic

messenger who came to Jehu as a "madman" (*meshugga*; II Kings 9:11), indicate that they were often held in contempt; yet the same texts reveal that such spokesmen for the deity were feared and that their words and deeds were taken with utmost seriousness. Prophetic bands continued to exist for centuries (I Kings 22:6; II Kings 2:3; Amos 7:14), and from their ranks, it may be inferred, the more individualistic and independent prophetic spokesmen were often drawn.

Early Prophetic Personalities.—Among the many individual prophets named in the traditions covering the 10th and 9th centuries, two stand out in particular: Nathan in the time of David and Solomon, and Elijah (*q.v.*) in the reign of Ahab. Nathan's severe indictment of David for adultery and murder (II Sam. 12) and Elijah's denunciation of Ahab for his theft of Naboth's vineyard (I Kings 21) reveal the prophetic understanding of the sovereign authority of God over the highest human authorities. These denunciations also display another fundamental concern of the prophets: the God of Israel will not tolerate oppression of the weak by the strong. Abuse of power is repugnant to the Lord of Israel; it is at once an attack upon the Lordship of God and a refusal on the part of man to live a responsible and righteous life under God's Lordship. Elijah's assault upon the worship of the Phoenician Baal, which was sponsored in north Israel by Jezebel, also illustrates the prophetic insistence upon the sovereign Lordship of God. If Yahweh is God, he and he alone should be worshiped and served; if Baal is God, then Baal alone deserves worship and allegiance. The people could not, in Elijah's judgment, continue to "go limping with two different opinions" (I Kings 18:21). The issue was decided on Mt. Carmel, when the people cried out, "The Lord, he is God." This practical monotheism was to find even more cogent expression in the subsequent prophetic tradition.

Major Prophetic Collection.—The Old Testament collection entitled the Latter Prophets by the later Jewish community contains a massive body of prophetic literature preserved under the names of 15 individual prophets: Isaiah, Jeremiah, and Ezekiel (the "major" or larger prophetic books; Daniel is placed with these in the English Bible) and Hosea, Joel, Amos, Obadiah, Jonah, Micah, Nahum, Habakkuk, Zephaniah, Haggai, Zechariah, and Malachi (the "minor" or shorter prophetic books; the "Twelve"). The book of Isaiah contains at least 16 chapters (ch. 40-55) which stem from a prophet active among the Judean exiles in Babylonia c. 540 B.C. who is referred to as the Second Isaiah or Deutero-Isaiah (*see* ISAJAH, BOOK OF). All of the prophetic books appear to have undergone a process of editing and arrangement which led, in a number of instances to the addition of materials. It is probable that "schools" or circles within the Israelite community undertook to preserve and re-present the words and deeds of the major prophetic personalities. In Isa. 8:16-20, reference is made to that prophet's disciples (*limmudim*), to whom are entrusted the "testimony" and "teaching" of Isaiah.

It is not possible, therefore, to recover the exact words of the prophets of Israel. Yet from the circle of disciples has come a collection of materials which undoubtedly bear authentic witness to their words and deeds. It is a tribute to the power of these words and deeds that they should have been remembered, pored over, and recorded definitively for subsequent generations. The total prophetic collection probably assumed its present form no later than 200 B.C.

The prophets were also rather closely related to the Israelite cultic practices. They functioned in connection with the great festivals and ceremonies, particularly the festival at the end of the year when the covenant between Yahweh and Israel was renewed and the king was reinvested with authority under God's sovereignty.

Most probably the prophets served as mediators of the covenant between God and Israel; it would be wrong to dissociate them too sharply from priestly activities and responsibilities. Nonetheless, the prophets of Israel stood over against established religious traditions and customs and brought the divine Word of judgment against all efforts on the part of the community to secure its life by merely external or cultic means. The freedom of

God was to be protected at all costs.

Preexilic Prophets.—During the last half of the 8th century, prophecy in Israel assumed its definitive character. The prophets Amos and Hosea in north Israel, and Isaiah and Micah in Judah, drew with inexorable logic the consequences of belief in the Lordship of God over men and nations. Their messages differ in emphasis, but in all essential respects these prophets bear a common witness. Amos appeared in north Israel just prior to the rise of the Assyrian Empire to new heights under Tiglath-pileser III (745–727). The message of Hosea, Isaiah, and Micah is set in the context of Assyrian domination of Palestine and Syria; never far from view is the menace of this world power to the people of Israel. The word of the prophet is addressed to concrete situations and involves issues of life-or-death significance.

Central to the message of this group of prophets is the theme of divine judgment upon a faithless people. Israel has known God's blessing and protection (Amos 3:2) but has chosen to turn from God. The result must be severe judgment, possibly up to the point of annihilation of the people of God by God himself (Amos 9:8a). Amos pointed specifically to the corruption in public and private life within north Israel as the sign of the people's apostasy. Hosea developed the same theme and also saw in the people's dependence upon godless kings and foreign alliances a mark of their faithlessness to God. Idolatry, not clearly mentioned in Amos (but *see* 5:26), is bitterly attacked by Hosea. Isaiah catalogued the sins mentioned by Amos and Hosea and particularly stressed the sin of rebellion against the sovereign Lord (1:2). Micah's judgment upon Judah is essentially that pronounced by Amos upon north Israel.

God's judgment will be executed by the agency of a foreign invader. Amos does not seek to identify the invader, and the Assyrian Empire was still in a period of decline as the message of Amos was delivered. Hosea can speak of either Egypt or Assyria as the instrument of divine judgment (7:11; 9:6). Isaiah, however, refers to Assyria directly as the "rod" of God's anger (10:5), God's weapon to punish the rebellious people and cause the remnant left from the holocaust to return in faith and obedience to him. In face of such dire consequences, the people are summoned to return to God and be saved. Amos apparently holds out no hope that the people will do so (9:8b–15 are probably from a later hand).

Hosea, though equally pessimistic about the return of Israel to God, speaks of God's continuing love and compassion for the faithless bride (ch. 2) and for the rebellious son (ch. 11). God will not finally destroy his people; his love and mercy are not vitiated by the corruption and perversity of his people. And Isaiah is even more explicit in his hope for the future: from the devastation, a small remnant will be spared (10:22); God will raise up a deliverer from the seed of David who will fulfill the divine purpose for Israel and for the world (9:2–7; 11:1–9; *see* 2:2–4). In the meantime, Israel is to have faith; *i.e.*, she is to trust firmly in the faithfulness of God (7:9; 28:16; 30:15).

These words of hope for the future (the authenticity of which is denied by many scholars) by no means soften the severity of the divine judgment upon Israel. God's Lordship is the fundamental theme of these prophetic texts: God is God, and he will not tolerate perfunctory allegiance to his will. The total life of Israel is to be lived under his authority. God, the determiner of what is good for man, summons the individual and the people as a whole to seek him; to seek God is to seek the good (Amos 5:4, 6, 14). He demonstrates by his own righteousness and mercy the path of goodness and righteousness (Mic. 6:8). He and he alone has the power to save in time of trouble (Isa. 30:1–5; 31:1–3). Yet he calls upon man to seek and to follow the path that leads to peace and safety. He is the Lord of other nations as well as of Israel, whether or not these nations acknowledge his Lordship (Amos 1–2; Isa. 13–23). God has the power to destroy and the power to save. But man cannot presume to exercise the divine power as though it had been entrusted entirely to him. Not even the religious authorities can do so. The attacks of the prophets upon Israelite worship are designed to make this fundamental point clear. No multiplication of sacrifices and offerings can

safeguard the lives of a faithless people. Sacrifice and offerings are no substitute for obedience. A "religion" practised in isolation from political, military, economic, and family responsibility is no religion at all. God calls for the loyalty and devotion of the whole man, the whole people.

The words of hope point rather to the prophetic conviction that God's purpose for mankind will triumph, despite the sin of Israel and the nations. In Hos. 11 is depicted a struggle within the "heart" of God himself: how can he bring utter destruction upon a people whom he loves? He is God and not man; God will love his people freely (14:4) and will heal their faithlessness. God remains Lord even over his decision to punish his rebellious sons (Isa. 1:18), whom he summons to repentance and obedience. God judges, but he also forgives.

During the 7th century, the prophetic movement is little in evidence until after the death of the corrupt king of Judah, Manasseh. Under the regency and kingship of Josiah, however, new prophetic voices are heard. Zephaniah (*c.* 630) prophesied the utter destruction of God's people at the hands of a foreign invader and offered hope only that a remnant of the poor and the humble might be spared. Nahum (*c.* 612) prophesied the coming ruin of the hated Assyrian empire and its capital city, Nineveh. And Habakkuk (*c.* 605) pled with God for understanding of the ways of divine judgment: why should God punish his own people at the hands of a people less righteous than they? The answer given is in the spirit of Isaiah: "The just shall live in his faithfulness"; *i.e.*, the righteous man depends upon God's faithfulness even in time of disaster or despair, just as he continues actively to pursue righteousness in his daily life. Faith in God means both confidence in God's own faithfulness to his sovereign purpose and personal obedience to the divine will.

The chief prophet of this period is Jeremiah of Anathoth (*c.* 626 [perhaps 608]–*c.* 586). Jeremiah's message is essentially that of his predecessors Amos, Hosea, and Isaiah: the same denunciation of the sins of Israel appears, as does the same call to radical repentance and return to God (ch. 2–3). Jeremiah's message is distinctive, however, at a number of points. He sees in the rise of the Neo-Babylonian Empire (605 B.C.) the instrument of God's judgment upon Judah, but he does not anticipate, as did Isaiah, that God would send the invader away after he had done his task of devastation (*see* Isa. 37:28–29). Judah must go into exile and there be purged for the day of restoration and return to her own land. All efforts on the part of the Judaeans authorities to combat the power of Babylonia are constantly resisted by Jeremiah. On at least one occasion he was very nearly executed as a traitor because of his "weakening the hands" of the people (38:4).

Jeremiah struggled with God over the meaning of the divine message and over the delay in its fulfillment. For many years he prophesied doom—and nothing happened. Jeremiah's prayers, which are scattered throughout the first half of the book, demonstrate clearly the spiritual agony of the prophets of Israel. No other prophet has worked in such isolation from his community, ridiculed, persecuted, and despised. Yet he remained faithful to God through all trials and doubts until the destruction of Jerusalem in 587–586 B.C., when his words of judgment were finally fulfilled.

Jeremiah's hope for Israel is also distinctive. He anticipated the return of the exiles from Babylonia at a future date and the reconstitution of the people in their homeland. For this reason, he urged them to live responsibly in exile and even to pray for the peace of the land of their captivity (ch. 29). A day was to come when God would make a new covenant with his people, write his Law on their hearts, forgive their iniquity and remember their sin no more (31:31–34). Apparently Jeremiah did not share the great cosmic hopes of Isaiah. His more modest picture of the future involves the restoration of God's people upon their own land, but it does not include any restoration of the Temple, the sacrificial system, the old customs and laws. In this respect he differs sharply from Ezekiel as well as from Isaiah. For Jeremiah Israelite faith is dependent upon no external supports and safeguards. The Temple was destroyed by the very God whose dwelling place it was (*see* ch. 7 and 26). The Law of God was funda-

mentally an inward reality, not a collection of ordinances to be written down and preserved. Faith was for Jeremiah a matter of communion with the living God. The intimacy of the relationship between God and man has no more explicit depiction than in the Book of Jeremiah (and in the Psalms, where Jeremiah's influence can be observed). Indeed, the entire prophetic movement in Israel is marked by this interior relationship between God and man, a relationship which produces freedom and spontaneity in religious acts and in daily life.

The preexilic prophets received their messages from the deity in some form of immediate experience, according to their testimony. In their conflict with the false prophets, or in defense of the truth of their words before the community at large, they could only say "The Lord sent me" (Jer. 26:12). Other prophets could make the same claim. The criteria of the true prophet were never more than working guides for the community and for the prophets themselves. The test of history was the acid test: did the words spoken by the prophets come true, or did they not (Deut. 18:21-22)? The prophets who prophesied doom rather than peace were also considered to be the more serious and reliable spokesmen for the deity (I Kings 22; Jer. 23:16-17). Yet these criteria would not suffice. In Deut. 13:1-5, appeal is made to tradition: a prophet must speak in line with the fundamental understandings of Israelite faith; if he does not do so, he is to be ignored. Jeremiah's test is finally that of the interior experience of the prophet: the true prophet is one who has sat in the (secret) council of God (23:18, 21-22). No external criteria can finally determine the truth or falsity of the divine Word spoken through the prophet.

Prophets During the Babylonian Exile.—Ezekiel and the anonymous prophet known as Deutero-Isaiah prophesied, respectively, during the early and the closing years of Babylonian exile. Ezekiel was among the captives carried into exile by the forces of Nebuchadnezzar, in 597 (or perhaps 587) B.C. Prior to the fall of Jerusalem in 587, his message was a massive polemic against the corruption of Israelite worship in Jerusalem and Judah. His strange visions and symbolic actions are all designed to express God's wrath over the desecration of Judah's religious traditions; and the prophet's message, like that of Jeremiah, is that God will destroy the defiled Temple; God's glory will depart from it; and the people will be swept off into exile. After the fall of Jerusalem, however, Ezekiel became a pastor to the exiles. His words of encouragement and hope are mixed with denunciations of political and religious corruption, but their chief import is to inspire confidence in God and in his coming deliverance as well as to summon the community and its members to responsible and righteous conduct. The vast program for the reconstitution of the state of Israel (ch. 40-48) was not to be realized; yet this vision probably did much to preserve the exiles as a religious community and hold them in readiness for the deliverance which came some years later.

From the exilic community appeared a prophetic spokesman whose message has no counterpart in the entire prophetic tradition. Deutero-Isaiah composed a prophetic text in the form of a great liturgy which abounds in hope and exultation. The radical and explicit monotheism of this prophet grows out of his conviction that God is bringing to fulfillment his whole purpose for mankind—and the people need to be reminded that God both *can* and *will* accomplish this purpose. God the redeemer is also God the creator; the whole of creation has been for the sake of redemption. With varying themes and an opulent and repetitive style Deutero-Isaiah displays the imminent deliverance of the exiles, their return across the bleak desert, and their entrance into a restored Zion.

Interwoven with the above materials are four poems (Isa. 42:1-4; 49:1-6; 50:4-9; 52:13-53:12), known as the Servant Songs, in which the most profound hope of the prophet finds expression. Israel, or a chosen representative of Israel (or both), is seen to be God's specific instrument for the redemption of mankind. God's Servant will bring justice to the world (42:1); he will be a light to the nations (49:6), so that God's salvation may reach the ends of the earth. Though faint and despondent, he will be vindicated before his oppressors and adversaries (50:4-9), and on the

day of his exaltation the kings of the earth will discern that he has been wounded for their transgressions, smitten for their iniquities, that they, through his stripes, might be healed (53:5). This Suffering Servant of the Lord represents and embodies the mission of Israel in the world: God's people have been chosen not merely for privilege but above all for service (*see* Amos 3:2); through this representative Israelite, men and nations will come to know the meaning of their own lives and will be drawn to the living God, the only source of life and blessing.

Postexilic Prophets.—During the Babylonian exile, prophets continued to work in the devastated community of Judah. One of these, Obadiah, uttered bitter invectives against the Edomites, who gloated over the fall of Jerusalem and helped the Babylonians to round up fugitives from the besieged city. In 520 two prophets arose who were of great significance in the rebuilding of the Judaean state under Persian rule: Haggai and Zechariah. Although these prophets were particularly concerned with the reconstitution of the Judaean state and the reestablishment of its religious life, they continued to maintain the prophetic judgment upon merely external or half-hearted religious practices. Appeal was made to the "Former Prophets" (Zech. 1:4; 7:7) whose judgments from God had been confirmed in history. The postexilic prophets maintained with rigour the older prophetic insistence upon righteous conduct which shows that God's authority is taken seriously (Zech. 7:9-10; 8:16-17). And they point, in manifold ways, to the coming of God's day of triumph over all forces in opposition to his will (Zech. 9:9-10; Joel 2:28-32; Mal. 4:1-5). The heritage of the prophets is firmly embedded in the main stream of Jewish life and thought; and it also finds its particular expression in the apocalyptic element within Judaism (*see* APOCALYPTIC LITERATURE).

POSTBIBLICAL PROPHECY

Early Christian Church.—In the early organization of the Christian communities (Acts 11:27; Eph. 4:11; I Cor. 12:28) prophets are mentioned, ranking next to apostles. Sometimes itinerant, sometimes settled, they were the evangelists of the early Church, credited with a direct spiritual inspiration and gift (*charisma*) for enlightenment and edification. Men can be appointed to a regular office in the Church; they cannot be appointed to prophesy. These prophets were expected to provide intelligible utterances (I Cor. 14:29-32) and were thus differentiated from the ecstatic "speaker in tongues," while they were also distinct from the permanent local officials—catechists, deacons, presbyters, bishops. From the valuable information in the Didache it appears that the high regard felt for them lasted fully a century; yet their position was always precarious. At the end of the 2nd century the wild prophesying in the Montanist Party hastened the end (*see* MONTANISM). Armed with the now-accepted canon of Holy Scripture, the authorities ruled that ecstatic seizure did not emanate from God and that the prophets were not to accept gifts. Soon Christian prophets ceased to exist as a distinct class in the Church's organization.

Yet the prophetic dimension of biblical faith in the Jewish and Christian communities has continued to be a distinctive and dominant element in these communities and in the cultures under their influence. The sovereign Lordship of God, his concern for inwardness of faith and righteous conduct, his power to assess, judge, and recreate even the religious communities which affirm his Lordship—this prophetic theme is a legacy from the prophets of Israel which is vital to any religious community rooted in biblical faith. Prophetic faith always poses issues which are of life-and-death significance; "Seek the Lord and live" (Amos 5:6) is the abiding call of the prophet. (W. HA.)

Later Christianity and Judaism.—In Judaism and Christianity, the ancient prophetic and apocalyptic pattern could always provide a model for either immediate or eschatological realization. Thus the prophetic *charisma* of the primitive Church was claimed also in later periods by various groups and individuals. The Montanists and the "pneumatic" monks (*see* MACEONITUS) of the first

Christian centuries had their successors in, for example, the vagrant *prophetæ* on the eve of the first Crusade and in the children-prophets among the French Camisards (*q.v.*) at the end of the 17th century. The same biblical promises of a large-scale restoration of prophecy (Joel 1-2) which had already inspired the first Christians (Acts 2:16-21) also produced mass prophecy in Jewish messianic movements—*e.g.*, that centred on the person of Sabbatai Zebi (*q.v.*).

In Christian sects the prophetic and the chiliast (millenarian, adventist) elements were always closely intertwined (*see* MILLENNIUM). A less eschatologically oriented view was taken by the medieval Jewish philosophers, among them Maimonides, who held that prophecy was nothing but the illumination of the mind resulting from the perfection of the human intellect; *viz.*, from the contact of the latter with the divine principle known as the "Active Intellect." The prophet was thus the most perfect philosopher. Similar doctrines could also be held with a less philosophical and more gnostic or mystical emphasis (for example, the *Insan al-Kamil*, literally "the Perfect Man," in Islamic mysticism); the prophet is then the perfect man whose soul is united to the Divine Light or Essence. On this view prophecy is a state of mystical and illuminate perfection rather than an individual vocation or a social *charisma*.

ISLAM

In a sense Islam is the prophetic religion *par excellence*. It is the only historical religion, of whose origin we have detailed knowledge, that was founded by a prophet. In a wider sense it belongs to the biblical religions, since Mohammed (Muhammad) knew of the existence of the Old and New Testaments and was profoundly influenced by Jewish and Christian contacts. Zoroaster, too, though he was a priest, seems to have been a definitely prophetic personality, and the religion he founded exhibits a genuinely prophetic structure, but too little is known about his life and ministry to permit positive assertions; some scholars, in fact, describe him as a shaman rather than a prophet.

In the case of Mohammed, however, we possess not only a record which permits a reconstruction of his prophetic experience but also a highly developed theology expounding the nature and calling of the prophet. Whereas the formal characteristics of Mohammed's utterance (style, rhythmic prose, etc.) continue the pre-Islamic tradition of the inspired soothsayer (*kahin*), his religious interpretation of prophecy was determined by Jewish-Christian traditions, including religions influenced by them (*e.g.*, MANICHAISM; *q.v.*). Whatever the precise identity of the revelatory agent—whether Allah himself (*cf.* Koran, *sura* 75:16 f.) or an angel (Gabriel in *sura* 2:97)—Mohammed experienced an original call (*sura* 96?) and many subsequent revelations. From the Medina period on he described himself as a *nabi*, considering himself as the last in a series of *nabiyyun* sent by God (*sura* 6:83-86).

The Koran distinguishes two kinds of prophets: the *nabiyyun*, of whom there were many; and the "apostles," of whom, besides Mohammed, there were eight only (including the biblical Noah, Lot, Ishmael, Moses, and Jesus). The apostle (*rasul*) is not merely an inspired speaker but a lawgiver who brings a heavenly book. Muslim doctrine of apostleship is therefore inextricably bound up with the doctrine of Holy Scripture. God sent an apostle to each nation (*umma*); however, Mohammed, who was sent as an apostle to the Arabs, is not only the greatest but also the last (*khatam*, "seal") of the prophets. Hence Islam has no room for subsequent prophecy, unless the term is understood in the wider sense of inspiration and illumination (as in gnostic and mystical circles, particularly in certain Shi'ite sects), or of special and immediate guidance by God (*see* MAHDI).

PRIMITIVE RELIGIONS

Religious leaders or functionaries exhibiting certain prophetic characteristics can be found in most primitive religions. The recognition and description of primitive prophets is largely a matter of definition and of delimitation from the related phenomena of divination, magic, shamanism (*qq.v.*), and augury (*see* AUGUR). Situations of stress have frequently produced leaders showing a

certain resemblance to the biblical prophets: an initial spiritual experience or "call," followed by passionate appeals to the prophet's group demanding reform of morals and manners—frequently in terms of a return to the ways of the ancestors—predicting some kind of general catastrophe, and promising a more or less imminent salvation (liberation from white rule, riches and health, return of the ancestors or of a mythical culture-hero, etc.). The emphasis on the two main foci of prophetic preaching, reformation and eschatological preparation, may vary considerably. Most of the prophetic movements that have been studied in detail occurred after contact with whites, and hence many prophets show signs of Christian missionary influence.

In modern ethnological literature millenarian and messianic movements are often called prophetic. Examples from the North American area alone include the prophets Pope, leader of the Pueblo revolt against the Spaniards in 1680; Tenskwatawa and his brother Tecumseh (*q.v.*), leaders of the Shawnee resistance in 1805-13; Smohalla, active 1850-90; the "Prophet Dance" movement which, in its turn, influenced the "Ghost Dance" outbreaks (*see* GHOST DANCE). Whereas the "nativism" of the Ghost Dance prophets was definitely millenarian in character, the "glad tidings" of the Seneca prophet Handsome Lake (active 1799-1815), founder of the Iroquois Long House Religion, was nativistic in a more reformative way. Analogous phenomena have occurred in great numbers in Africa, Oceania, and many other parts of the world. (*See also* CARGO CULTS; NATIVISTIC MOVEMENTS.)

These millenarian prophetisms should be distinguished from sectarian prophetisms. The latter, although they too are often reactions to frustration, oppression, and the "colonial situation," are in many ways similar to revivalist outbreaks in Western Christianity (*see* REVIVALISM). The proliferation of dissident native churches generally takes place under the leadership of prophets who combine Christian ideas concerning the prophetic gift with traditional native patterns of possession, divining, and curing.

OTHER EXAMPLES

Revelations and messages by prophetic founders or reformers, leading to the establishment of new religious groups similar to Christian sects or "dissident churches," occur also outside the Christian orbit. One of the most striking examples in modern history is provided by the remarkable proliferation of religious groups—somewhat ineptly called "New Religions"—in modern Japan (*see* JAPAN: *The People: Religion: New Religious Cults*). Many of these groups, growing from a Buddhist, Shintō, or syncretistic soil, were founded by prophets (or, frequently, prophetesses) who combined some of the ancient shamanistic traditions of Japan with a prophetic sense of mission. This development is particularly interesting in view of the fact that Buddhism has produced many enlightened teachers, masters, and patriarchs but no spiritual leaders of the prophetic type. Perhaps the most outstanding exception to the rule is Nichiren (1222-82; *see* BUDDHISM), whose fanaticism, uncompromising radicalism, sense of mission, and profound conviction of being called to save the Japanese nation give his preaching a prophetic character.

(R. J. Z. W.; W. H. A.)

PROPORTIONAL REPRESENTATION (P.R.), the name for the principle that the distribution of seats in a representative assembly should reflect as exactly as possible the distribution of the electors' votes among the competing parties (and independents, if any).

To its advocates the case for P.R. is fundamentally the same as that for representative government: *i.e.*, only if the assembly represents the full diversity of opinion within the nation can its decisions be regarded as the decisions of the nation itself. Holding an election is like holding a census of opinions as to how the nation shall be governed.

P.R. is opposed on grounds of both principle and expediency. In principle, its opponents hold that in an election the nation is making a decision, a choice; that the function of the electoral system is to achieve a consensus rather than a census of opinions. To make it possible for small sections of opinion to be represented is to encourage the formation of separate parties, and their mutual bargaining within the assembly leads to a weakening of the government and the processes of government. The electors in these circumstances, in fact, have less direct choice of government. The experiences of the Weimar Republic in Germany (1919-33) and of the Fourth Republic in France (1946-58) are quoted as evidence for the truth of this argument. In order to achieve a system of two parties it is necessary for the electoral system to promote the cohesion of opinions into large forces by devices which reward the stronger parties and penalize the weaker ones. There are various "majority" systems which are intended to achieve these purposes.

Supporters of P.R. reply that the relations between electoral systems, party systems, and the stability and effectiveness of governments are more complex than the opponents of P.R. believe. Belgium, Denmark, Finland, Ireland, Luxembourg, the Netherlands, Norway, and Sweden all apply P.R.; each has only a few parties of real importance and each has usually had stable, durable, and effective governments. On the other hand, countries not applying P.R. have not always had two strong parties; thus the United Kingdom has at times had a complex party system (*e.g.*, 1885-1914 and 1922-31) and precarious governments; in the United States the system of two major parties masks a multiplicity of informal and unstable factions and alliances transcending party divisions in Congress. Moreover, when the electoral system does not provide for proportional representation, an election may result in the majority of seats being won by a party receiving fewer votes than one of its opponents. Thus the Conservatives won more seats but fewer votes than Labour in the British general election of 1951; the Republicans won more seats in the electoral college but fewer popular votes than the Democrats in the U.S. presidential elections of 1876 and 1888 and therefore won the presidency; the parties supporting the Nationalist leader D. F. Malan won more seats but fewer votes than the parties supporting J. C. Smuts in the South African general elections of 1948 and 1953. Advocates of P.R. would argue that results such as these make nonsense of representative government.

The principle of P.R. was first formulated systematically in the middle of the 19th century by C. C. G. Andrae in Denmark and T. Hare and J. S. Mill in Britain. Many electoral systems have been devised to apply it. The one most advocated by the Electoral Reform Society in Britain and the Proportional Representation League in the United States is that of the single transferable vote (S.T.V.) in multimember constituencies, as used in Ireland (since

1922), Tasmania, Malta, and the Australian and South African senates. Voters number the names of the candidates on the ballot paper in order of preference, as for the alternative vote (*see below*). Ballot papers are first counted according to their first preferences. Any candidate who obtains a Droop quota (named after the discoverer of the system, the Belgian H. R. Droop), *i.e.*, $\frac{\text{no. of total valid votes cast}}{\text{no. of seats} + 1} + 1$, of first preferences is de-

clared elected; *e.g.*, in a five-member constituency, one-fifth of the votes is not the smallest number of votes required by a candidate in order to secure a seat; six candidates could each get one-sixth of the total votes, but only five could get more. Any candidate polling even one vote more than one-sixth will be one of the five elected members. Where a quota is exceeded, all the votes of a successful candidate are sorted out for second preference, the total for each other candidate being noted. The number of votes transferred, however, is only that of the surplus over and above the quota; *i.e.*, if a candidate's surplus is one-third of his votes, the number of votes passed on to each other candidate is one-third of the preferences indicated for each of them. Any surplus among subsequently successful candidates is similarly transferred, and so on, if necessary. If any seats are still vacant, the candidate with the least papers is eliminated, and all his papers transferred to second preferences, and so on, if necessary, until all seats are filled by candidates obtaining a quota. In this way the results reflect accurately the preference of the electors and therefore their support both for individuals and for parties.

"List systems" for achieving proportional representation are used extensively on the continent of Europe. In these systems the elector votes for a list of candidates; each list is normally presented by a party organization; each party gets a share of the seats proportionate to its share of the votes. There are various alternative mathematical rules for achieving this. The two principal ones are the largest remainder rule—any seats still remaining after the quota has been filled going to the party with the largest remainder of votes; and the highest average rule, the d'Hondt rule (from its inventor, Victor d'Hondt) where the average number of votes required to win one seat is as nearly as possible the same for each party. The seats a party wins are allocated to its candidates in the order in which they are named in its list; there are various methods of enabling the elector to express preferences between the candidates of the list he supports or even to enable him to split his vote between several lists but none of these has proved as flexible and effective as the S.T.V.

Where the majority representation principle exists, the simplest system is one in which each constituency returns one representative, and the candidate with more votes than any other wins the seat, as in Britain, Canada, New Zealand, and the United States. Multimember constituencies can, however, be used; in these electors may be allowed to vote either for lists of candidates or for individual candidates. The principle is carried to its logical conclusion when the whole country is used as a constituency and the list with most votes gets all the seats, as in the Gabon Republic and Togo in 1961.

Variants of the majority system are intended to ensure some representation for minorities. Provision may be made for two ballots. At the first ballot a candidate (or list) is victorious only if he (or it) has the support of more than half of the electors voting; if an "absolute majority" of this kind is not obtained, then a second ballot is held at which the candidate (or list) with most votes ("a relative majority") is victorious; this system has been much used in France. Competition at the second ballot may be free or restricted to the two leading candidates of those who stood at the first ballot and who still wish to compete (as in France since 1958). Yet the second ballot system is not a means of applying the principle of proportional representation; thus in France in 1958 the Communists' share of the votes was ten times their share of the seats. The single transferable vote in single-member constituencies (usually called the alternative vote) is a more refined and more protracted form of the second ballot; in marking preferences on this ballot paper the elector is in effect voting in successive "second ballots" until one candidate secures an absolute

majority. However, as there is only one seat to be filled, the candidate with over half the votes will get it. The limited vote and the cumulative vote are further examples. In the strictest form of the limited vote the elector has only one vote (the single nontransferable vote in multimember constituencies and employing the Droop quota); this system has been used in Japan since 1900, and in the elections when voting has been free the results have been very nearly proportional. In other forms, the elector has fewer votes than there are seats to be filled. In the cumulative vote in multimember constituencies the elector has as many votes as there are seats to be filled, but he can give two or more votes to a candidate instead of only one vote. This is used for the state legislature in Illinois, where it has ensured representation for minorities but does not guarantee that the representation will be proportionate to the parties' shares of the votes.

Some countries have developed mixed systems applying the principles of "majority" and "proportional" representation. Thus in the Federal Republic of Germany since 1949 each elector has had two votes. Half the members in the parliament are elected in the single-member constituencies. The remaining seats are filled proportionately by the list system in multimember constituencies. The number of seats a party gains in the single-member constituencies is deducted from the total number of seats to which it is entitled, so as to obtain the number of seats which will be filled by the party from its lists. This system slightly favours the larger parties but is essentially one providing for proportional representation. In France in 1951 the list system of P.R. used at the previous elections was modified so that in any provincial constituency any party or interparty alliance which secured an absolute majority of the votes would win all the seats; this change was intended to weaken the Communist Party and Gen. Charles de Gaulle's Rassemblement du Peuple Française. In Italy in 1953 the list system of P.R. used at the previous election was modified so that if a party or alliance won an absolute majority of votes in the country as a whole it would get three-fifths of the seats; in fact, no party or alliance succeeded and the P.R. list system was applied as before. See also DEMOCRACY; REPRESENTATION.

(P. W. C.)

PROPOSITION. In scholastic and traditional logic, a proposition was understood as an expression in words having the meaning of an assertion. An example is Petrus Hispanus, c. 1245, "Propositio est oratio verum vel falsum significans indicando" ("A proposition is a statement indicating a true or false meaning"). Thus a proposition is not simply a declarative sentence, in the grammatical sense, but is such a sentence taken together with its meaning. Consequently, propositions may be different even though the sentences are the same (e.g., *I am hungry*, uttered by two different persons), and, although this consequence is less emphasized by traditional writers, propositions are different when the sentences are different and even if the meaning is the same (e.g., *Tempus fugit* and *Time flies*).

The usual scholastic term was the Latin *propositio*—first found in this meaning in the writings of Lucius Apuleius, c. 150, and Manlius Severinus Boethius, c. 500. However, *enuntiatio* (enunciation)—a term taken from Cicero—was also employed, and some of the scholastics used this as the general term, reserving *propositio* for some more special meaning.

This scholastic-traditional notion of a proposition is inconvenient or unsatisfactory in many contexts because of its dependence on the particular form of expression in words, or on a particular language. Hence the different notion of a mental proposition (*propositio mentalis*) came to be introduced, and also, chiefly later, that of a judgment (*iudicium*).

According to William Ockham, and later scholastics who followed him, the mental proposition must be formed internally before a corresponding proposition in words is put forward. It is not of any language. Its parts are mental terms or concepts, which

are analogous to the spoken or written terms and share with them all properties essential to the meaning, but not such purely grammatical properties as having a particular (grammatical) gender or belonging to a particular declension or conjugation.

The notion of a judgment, as the mental act of assent or dissent, has some mention in the writings of various scholastics, and was made an explicit part of the treatment of logic by Petrus Ramus and later by such logicians as Isaac Watts (1725) and Christian Wolff (1728). It was still later that the definition of a proposition as a "judgment expressed in words" became a commonplace.

Immanuel Kant, and many traditional logicians who have followed him, replace the consideration of propositions almost entirely by that of judgments. Thus Kant speaks usually, though not always, of an analytic or synthetic judgment (German, *Urtheil*) rather than proposition (German, *Satz*), of a categorical judgment, etc.

However, the mental proposition and the judgment have a psychological reference which may often be as unsatisfactory as the dependence on a particular language which is involved in the traditional notion of a proposition. For some purposes at least there is needed a more abstract notion, independent alike of any particular expression in words and of any particular psychological act of judgment or conception—not the particular declarative sentence, but the content of meaning which is common to the sentence and its translation into another language—not the particular judgment, but the objective content of the judgment, which is capable of being the common property of many. Such an abstract notion may be seen in the Stoic *Lekta* (see LOGIC, HISTORY OF: Stoics and Megarians) and the *complexe significabilia* of some 14th and 15th century scholastics, but these ideas fell into oblivion and were reintroduced in different terminology in modern times. By modern logicians the word "proposition" has come to be used for the abstract notion, and we shall therefore here distinguish between *proposition in the traditional sense* and *proposition in the abstract sense*.

Bernard Bolzano attributes the use of *propositio* for proposition in the abstract sense to G. W. von Leibniz in *Dialogus de Connectione inter Res et Verba*. This may be a misunderstanding. But this dialogue does set forth clearly one important ground of the need for the abstract notion. An explicit distinction between the sentence and the proposition (in the abstract sense) which the sentence expresses is made by Bolzano in his *Wissenschaftslehre* of 1837, where *Satz an sich* is used for the latter. Gottlob Frege in 1892 uses *Gedanke* for the sense of a declarative sentence, giving to this German word (as he explains) an objective, rather than its more natural subjective, meaning. *Proposition* is used in the abstract sense by Bertrand Russell in *The Principles of Mathematics* (1903), where Russell recognizes that Frege's *Gedanke* is approximately "what I have called an unasserted proposition," and in *Principia Mathematica* A. N. Whitehead and Russell speak of "what we call a 'proposition' (in the sense in which this is distinguished from the phrase expressing it)." Russell also uses *proposition* in the traditional sense, e.g., in *Introduction to Mathematical Philosophy*, defining a proposition as "a form of words which expresses what is either true or false"; but more recent writers have generally followed him in the abstract usage. See also LOGIC.

PROPYLAEA, the name given to porches or gatehouses at the entrance of sacred or other enclosures in Greece; propylaea usually consisted, at their simplest, of a porch supported by columns both without and within the actual gate. The name is especially given to the great entrance hall of the Acropolis at Athens, which was begun in 437 B.C. by Pericles. Probably because of political difficulties and the outbreak of the Peloponnesian War, the building was never completed according to plan, but the portion that was built was among the chief glories of Athens and afforded a model to many subsequent imitators. The architect was Mnesicles; the material Pentelic marble, with Eleusinian blackstone for dados and other details.

The plan of the Propylaea consists of a large square hall, from which five steps lead up to a wall pierced by five gateways of graduated sizes, the central one giving passage to a road suitable for beasts or vehicles. On the inner side, facing the Acropolis, this wall is faced with a portico of six Doric columns. At the other end of the great hall is a similar portico facing outward; and between this and the doors the hall is divided into three aisles by rows of Ionic columns. The western or outer front is flanked on each side by a projecting wing, with a row of three smaller Doric columns between antae at right angles to the main portico.

EAST FACADE OF THE PROPYLAEA, ON THE ACROPOLIS, ATHENS

The north wing is completed by a square chamber which served as a picture gallery, but the south wing contains no corresponding chamber, and its plan has evidently been curtailed; its front projected beyond its covered area, and it is finished in what was evidently a provisional way on the side of the bastion before the little temple of Athena Nike.

From this and other indications W. Dörpfeld inferred that the original plan of Mnesicles was to complete the south wing on a plan symmetrical with that of the north wing, but opening by a portico on to the bastion to the west; and to add on the inner side of the Propylaea two great halls, faced by porticoes almost in a line with the main portico, but with smaller columns. This would have interfered with sacred objects such as the precinct of Artemis Brauronia and the altar of Nike, and the architect was probably forced to modify his plan even before work on the building stopped. The Propylaea were approached in Greek times by a zigzag path, terraced along the rock; this was superseded in Roman times by a broad flight of steps. In medieval times the Propylaea served as the palace of the dukes of Athens; they were much damaged by the explosion of a powder magazine in 1645. The tower of Frankish or Turkish date that stood on the south wing was pulled down in 1874. (See also GREEK ARCHITECTURE.)

The term is also applied to various monumental gateways of modern times, especially in Germany. Examples are the propylaea at Munich (1862) and the Brandenburg Gate in Berlin (1784).

See W. J. Anderson and R. P. Spiers, *The Architecture of Ancient Greece*, rev. by W. B. Dinsmoor, new ed. (1950); D. S. Robertson, *A Handbook of Greek and Roman Architecture*, 2nd ed., corrected (1943). (E. Gr.; C. M. Rn.)

PROPYL ALCOHOLS. Two compounds, both with the formula C_3H_7OH , are known by this name, and both are widely used.

Normal propyl alcohol, $CH_3CH_2CH_2OH$, is obtainable as a by-product in the synthesis of methyl alcohol by condensing carbon monoxide and hydrogen in the presence of a zinc-chromite or zinc-cobalt-chromite catalyst at $400^\circ C$ under 200 atm. pressure. It is a colourless, fragrant liquid boiling at $97.4^\circ C$ and miscible with water in all proportions. It cannot be separated from water by distillation since the two compounds form an azeotropic mixture. *n*-Propyl alcohol, also known as 1-propanol, occurs in fusel oil and may be prepared by any of the synthetic methods applicable to primary alcohols. (See ALCOHOL.) It is used in the preparation of lacquers, in organic chemical synthesis,

and as a solvent for many materials.

Isopropyl alcohol, $(CH_3)_2CHOH$, is manufactured on an extensive scale from propylene, $CH_3CH=CH_2$, obtained by the cracking of petroleum. This olefin is absorbed in sulfuric acid, the liquid is diluted with water, and the mixture is then distilled, with isopropyl alcohol being obtained. It is a colourless, fragrant liquid boiling at $82.7^\circ C$. It is used as a solvent, as a deicing and antistall agent in liquid fuels, and as a reagent in organic chemical synthesis. Its alternate name is isopropanol.

PROSE, the plain speech of mankind, when used without reference to the rules of verse (*q.v.*). As a literary term, it is generally opposed to poetry (*q.v.*), but because a definition of poetry involves metaphysical considerations, literary prose may be best defined as including all forms of literary expression not metrically versified. Its derivation from the Latin adjective *prosus* (earlier, *prorsus*), "direct," or "straight," has led at some periods to the theory that prose should be plain and straightforward, and should properly deal with the statement of what is true or provable in fact and reason.

Three main kinds of prose may be distinguished: descriptive (of action, people, places, or things); explanatory or expository; and emotive. In any prose work all may be found; thus a narrative may be primarily descriptive, but may include passages of explanatory and emotive prose. Descriptive prose includes narrative of all kinds: the prose romance (see ROMANCE); the novel and short story (*qq.v.*) and their variants (*e.g.*, mystery and detective stories, science fiction, and children's literature, *qq.v.*); autobiography and biography, the essay and the diary (*qq.v.*), the letter and the memoir, the "character" (see ENGLISH LITERATURE: *Early 17th Century*); accounts of travel and exploration; and those writings on scientific subjects that aim at describing, rather than explaining, the natural world. Explanatory or expository prose includes writings on science, law, philosophy, theology, morals, political science, history, and criticism. It may be objective, didactic, or persuasive in character, and may also include descriptive and narrative elements (in historical and scientific works, for example). Although often most nearly approximating to the idea of prose as "plain," explanatory prose may rise to poetic heights. (See also HISTORY: *Historiography*; CRITICISM; etc., for some account of writings in this type of prose.)

Emotive prose, aimed at inducing feeling rather than thought, is found in polemical works (see PAMPHLET), in oratory (*q.v.*), in the sermon (see PREACHING); and also in fictional, historical, scientific, philosophical, and critical writing. Much journalistic prose, though also descriptive and explanatory, is emotive in intention. Much biblical prose is primarily emotive: a fact that has increased the difficulties of translation (see BIBLE, TRANSLATIONS OF).

For a historical account of the development of prose in various languages, see articles on the national literatures: AMERICAN LITERATURE; ENGLISH LITERATURE; FRENCH LITERATURE; etc. See also STYLE, LITERARY; RHETORIC; DRAMA; DRAMATIC CRITICISM; NEWSPAPER; PERIODICAL; SATIRE; and articles on prose works and writers. See also the bibliographies to these articles.

PROSECUTION, the procedure by which the law is put in motion to bring to trial a person accused of crime. Constitutionally, maintenance of order is one of the functions of executive government, the whole of which, in the United Kingdom, is carried out in the name of the crown. In this sense the crown can be said to prosecute, and the prosecution is often referred to as "the crown." In theory, the individual who has suffered from the crime is at liberty to conduct the prosecution himself, but rarely does so. In practice, most prosecutions are undertaken by the police, on the basis of complaints made to them. The more serious crimes, such as murder, are prosecuted by a legal officer of the government. The English procedure does not centralize all prosecutions for crime in a public official or department and thus differs from the system employed in Scotland and continental European countries, as well as from the American system.

In the United States, crimes against the federal government are prosecuted by appointed United States attorneys, who act under the supervision of the attorney general. In the states, prose-

cution is by district or county attorneys. These usually are elected officials and enjoy varying degrees of autonomy from the supervision of the state attorney general; the latter may, however, be empowered on occasion to intervene and conduct a prosecution himself.

(H. L. Pr.)

PROSELYTE, a word that has come to mean a convert to any religious faith but that originally (Greek *proselytos*) meant a convert to Judaism. In Hebrew the verb formed from the noun "stranger" is not "to estrange" but "to disestrange"—that is, to remove a man from stranger's status by converting him into a Jew. In its very morphology the Hebrew language thus records a yearning for converts.

According to the Bible, even proscribed Canaanites lived with their Israelite hosts (I Kings 9:20-21) and apparently accepted at least some precepts of the religion of Israel. On most solemn occasions, such as the final covenant of Moses (Deut. 29:10, "the sojourner who is in your camp") and the reading of the Law on Mt. Gerizim and Mt. Ebal (Josh. 8:33-35), strangers stood alongside native-born Israelites. But it was apparently in the days of Ezra that the rite of formal conversion to Judaism—by baptism, circumcision, and a Temple offering—was developed (Neh. 10:29 and Rashi *ad loc.*). In subsequent centuries, particularly under Rome, there were so many converts to Judaism that Jews came to number almost 10% of the population of the Roman Empire—a percentage which could not have been accounted for solely by natural increase. The Jewish quest for converts is reflected in Jesus' statement that "you traverse sea and land to make a single proselyte" (Matt. 23:15; cf. Midrash Genesis Rabba 28:5), as well as in the ascription of proselyte forebears—even wicked forebears like Sisera, Haman, and Nero—to such worthies as Abtalion, Rabbi Akiba, and Rabbi Meir. The conversion of the royal family of the Kingdom of Adiabene is related by Josephus.

After the Theodosian Code (effective Jan. 1, 439) declared conversion of a Christian to Judaism a capital offense, the quest for converts had to be restrained; and in the course of time what was begun as discretion came to be regarded as policy. Still, throughout the ages individuals, particularly priests and noblemen, converted to Judaism. In modern times even entire communities have become proselytes; in the 1940s the villagers of San Nicandro in southern Italy joined Jewish ranks, and most of them migrated to Israel. Among the mass conversions to Judaism, that of the Khazars in the 8th century is noteworthy (see KHAZARS).

Braude, *Jewish Proselytism in the First Five Centuries of the Common Era* (1940); Elena Cassin, *San Nicandro: the Story of a Religious Phenomenon* (1959). (W. G. Br.)

PROSERPINE, generally accounted the Latin form (*Proserpina*) of Persephone. See PERSEPHONE.

PROSODY, CLASSICAL. Ancient Greek metre differs fundamentally from modern English metre in that it is based not on stress but on quantity. Greek verses are composed of comparatively complicated and rigid patterns of long and short syllables. Most Latin verse too is composed on a quantitative system in imitation of Greek.

Greek.—The length of a syllable is determined by the length of the vowel sound contained in it: ω , η and diphthongs are long by nature; α , ι , υ may be long by nature (e.g., $\chi\omega\rho\alpha$, $\lambda\upsilon\omega$, $\dot{\iota}\upsilon\epsilon\rho\omicron\varsigma$). Vowels with ι subscript or a circumflex accent are long.

A vowel may become long by position when followed by two or more consonants, or by the letters ζ , ξ , ψ ; e.g., $\dot{\epsilon}\lambda\pi\dot{\iota}\zeta\omicron\nu\kappa\epsilon\alpha\rho$. But certain combinations of consonants, known as "mute and liquid," do not invariably lengthen the preceding vowel. Such combinations are: $\pi\lambda$, $\phi\lambda$, $\kappa\lambda$, $\chi\lambda$, $\tau\lambda$, $\theta\lambda$, $\kappa\mu$, $\tau\mu$, $\theta\mu$, $\pi\nu$, $\phi\nu$, $\kappa\nu$, $\chi\nu$, $\theta\nu$, $\tau\nu$, $\pi\rho$, $\phi\rho$, $\kappa\rho$, $\tau\rho$, $\theta\rho$. The letters β , γ , δ lengthen the preceding vowel always when followed by μ or ν , usually when followed by λ , but not when followed by ρ . In Sappho and Alcaeus combinations of mute and liquid almost always lengthen the preceding vowel; in Homer, Pindar and Bacchylides more often than not; in Attic drama usually not.

Elision.—When a word ending with a short vowel is followed by a word beginning with a vowel, the final vowel of the first word is

usually omitted, e.g., $\tau\omega\nu\delta'$ ἀπαλλαγῆν.

Epic Correption.—In Homer a final long vowel or diphthong may be shortened when the following word begins with a vowel, e.g., $\dot{\epsilon}\gamma\omega\upsilon\delta'$.

Crisis.—Certain short words ending in a vowel may fuse with the initial vowel of the following word; e.g., $\kappa\alpha\dot{\iota}\epsilon\mu\epsilon$ becomes $\kappa\acute{\alpha}\mu\epsilon$.

Synzeesis.—Certain pairs or groups of vowels other than diphthongs may sometimes be scanned as one syllable; e.g., $\epsilon\omega$, $\mu\eta\upsilon$.

Hiatus.—Where a final vowel is followed by an initial vowel without either vowel being in any way affected, there is said to be "hiatus." In many apparent hiatuses in Homer the consonant γ ("digamma") was originally present, although not written in the manuscripts. The digamma is sometimes present in Pindar.

Greek verse is of two main types: spoken, or "stichic," and sung, or lyric.

Greek Lyric Verse.—Some lyric verse is composed in set stanzas, notably the sapphic and alcaic (*q.v.*), but most in "strophae" (see STROPHE), stanzas, often long and complicated, composed according to the poet's fancy. These stanzas may be analyzed into verses. The Greek verse is roughly equivalent to the line in English poetry, although one verse is often printed as more than one line in Greek texts. The end of a verse always coincides with the end of a word. When a verse ends with a vowel and the following verse begins with a vowel there is hiatus. The last syllable of a verse is always, in principle, long. If a short syllable occurs at the end of a verse, it is counted as long and called *brevis in longo*.

Each verse consists of one or more "cola" ($\kappa\acute{\omega}\lambda\omicron\nu$ ["limb"]). Some cola are analyzable into "metra" ($\acute{\mu}\epsilon\tau\rho\omicron\nu$ ["measure"]). The elements used in the composition of both metra and cola are: long (—), short (v), anceps (x, meaning that the position may be occupied by either a long or a short syllable), biceps (w, meaning that the position may be occupied by either one long syllable or two short ones). Thus x—v— is described verbally as "anceps, long, short, long," and —w— as "long, biceps."

Metra.—Iamb (x—v—), trochee (—v—x), dactyl (—w—), anapaest (basically —v—v—, but all four elements are bicipitia), ionic (w—v—), cretic (—v—), choriamb (—w—v—). Cola are usually formed of two or more metra of the same type and are named according to the number of metra they contain; e.g., ionic dimeter v—v—|v—v—. (See IAMB; IONIC METRE; TROCHEE; DACTYL; ANAPAESE; CHORIAMBIC VERSE.)

Catalexis.—Many types of colon may be varied by the omission of one quantity at or near the end. Thus, x—v—|v— is a catalectic iambic dimeter; v—v—|v— is a catalectic ionic dimeter.

In the following types the cola are not analyzable into metra. **Aeolo-Choriambic.**—Basic constituents: anceps, choriamb. —w—v—. Two ancipitia commencing the colon form the "aeolic base." A common aeolo-choriambic colon, the "glyconic" (*q.v.*), consists of base and —v—v—v—. Longer cola, the so-called "asclepiads," are formed by the addition of one or two choriambic between base and —v—v—v— (see CHORIAMBIC VERSE).

Prosodiac-Enoplia.—Cola of this type combine single-short and double-short rhythm. They cannot be analyzed and are perhaps best regarded as prolongations of —v—v—v—. Examples are:

— v — v — v — v —
καρδιόδηκτον ἔμοι κρατυνεῖς
— v — v — v — v —
βιον ᾧ τε δοκεῖ ψεγαῖ.

Dochmiacs.—The dochmiac may be regarded as an unusually long and variable metron. It consists of anceps, two bicipitia, anceps, biceps. The most common forms are: —v—v—v—, —v—v—v—. Dochmiacs are confined to Attic drama.

Dactylo-Epitrites.—These occur in Attic drama, and about half the extant poems of Pindar are composed in this metre. Its most common constituents are —v—v—v— (hemiepes), —v— (cretic) and —w— (choriamb), which are linked together by ancipitia, usually long, to form compounds like

— v — v — v — v — v — v —
κλεινὰν Ἀκραγὰντα γεραῖρων εὐχομαι.

The link anceps may sometimes be omitted, and verses may be

gin with acephalous (headless) elements, e.g.:

Ἀσίας εὐροχόρου τριπόλι νάσον πέλας.

Several types of metre may be combined in the same stanza. Iambic trimeters and trochaic tetrameters in the spoken portions of drama. Such lines are always divided by word-end at or near the middle. If this division falls within a metron it is called "caesura" (marked thus:), if at the end of a metron "diaeresis." (For the rules governing caesurae and other features of stichic composition see HEXAMETER; IAMB; TROCHEE; ANAPAEST; ELEGY.)

Greek Stichic Verse.—This is composed in lines (στίχοι) of the same length and type: dactylic hexameters in Homer, etc., iambic trimeters and trochaic tetrameters in the spoken portions of drama. Such lines are always divided by word-end at or near the middle. If this division falls within a metron it is called "caesura" (marked thus:), if at the end of a metron "diaeresis." (For the rules governing caesurae and other features of stichic composition see HEXAMETER; IAMB; TROCHEE; ANAPAEST; ELEGY.)

Latin.—The Saturnian, probably the only indigenous type of Latin metre, was employed in the earliest Latin verse: epitaphs, ritual incantations, Livius Andronicus' translation of the *Odyssey* and Naevius' *Bellum Poenicum*. The scansion of the exiguous fragments of Saturnians that survive is disputed, and both accentual and quantitative systems have been proposed. Ancient metricians quote as a perfect Saturnian:

malum dabunt Metelli || Naevio poetae

which may be scanned quantitatively as catalectic iambic dimeter and ithyphallic (cretic, bacchiac). But few other surviving Saturnians can be scanned so. From the time of Ennius, Saturnians were ousted by metres imitated from Greek.

The length of syllables is determined as follows: Diphthongs are long. A single vowel followed by a single consonant may be long or short by nature; e.g., *mālus* "bad," but *mālus* "mast." A vowel followed by two consonants is long by position. The vowel *s* is not always lengthened if the second of the two consonants is *l* or *r*; e.g., *volūcri* or *volūcri*. If, however, the first consonant and the following *l* or *r* belong to different words, the preceding vowel is always lengthened; e.g., *arcebāt longe*. Vowels are always lengthened before *ll* and *rr*.

Elision occurs when a word ending with a vowel or a vowel and *m* is followed by a word commencing with a vowel; e.g., *con-tinuer(e) omnes, quamqu(am) animus*. The vowel *i* must be distinguished from consonantal *i*, printed in older texts as *j*; e.g., *vitīs Iaccho, Coeumqu(e) Iapetum*, but *auxilium iubeat, irē iubes*. Initial *h* does not count as a consonant; i.e., it does not lengthen or prevent elision (e.g., *omnis humo, monstr[um] horrendum*). In Latin texts elided syllables are printed, not replaced, as in Greek, by apostrophe.

The principal types of Greek metre used in Latin are dactylic hexameters and elegiacs. Horace uses various lyric metres, notably sapphics and alcaics (q.v.), asclepiads, glyconics, etc. (see CHORAMBIAC VERSE AND GLYCONIC). Catullus and Martial use the choliamb (see IAMB) and the "phalaecean" or "hendecasyllable," an aeolo-choriambic colon composed of base, — — — — —, bacchiac (— — —):

Cui dono lepidum novum libellum
arida modo pumic(e) expoliturum.

Iambic trimeters of Greek type are found in Catullus, Horace and Seneca (see IAMB).

The verse of republican comedy differs fundamentally from the metres enumerated above. The lines are analyzable into feet, not metra. The equivalent of the iambic trimeter, the "iambic senarius," consists of six feet, the last of which must be an iamb (—). In the other feet a spondee (— —), a tribrach (— — —), a dactyl (— — —), an anapaest (— — —) and even (especially in the first foot) a proceleusmatic (— — — —) may be substituted. There is usually caesura in the third foot, sometimes in the fourth:

ego quia non rediit filius quae cogito.

The iambic octonarius (eight feet) and septenarius (seven and a half feet) also occur in comedy.

The "trochaic septenarius" (equivalent of Greek trochaic tetrameter catalectic) is the commonest verse in comedy after the iambic senarius. The seventh foot must be a trochee (— —). Spondees, dactyls, anapaests and tribrachs may be substituted in the first six feet. There is usually diaeresis after the fourth foot:

ubi me dixero dare tanti testis faciet ilico.

In comedy the rules governing the length of syllables differ in some respects from those for other types of classical Latin verse. Syllables which would elsewhere be long must in comedy sometimes be scanned as short. Pronouns especially are often shortened; e.g., *ille, iste*. Adjacent vowels are often contracted into one syllable by synizesis, as *fuisse, seorsum*:

non fuit necess(e) habere; sed id quod lex iubet.

The reasons for these particularities are much disputed. Some metricians attribute them to the presence of stress; others deny that stress had any influence on Latin versification.

Study of Classical Metre.—The most important ancient work on metre which has survived is an abridgment of the treatise of Hephaestion (q.v.). This work, however, records theories formulated when the principles of classical metre were no longer well understood. His chief mistake was to attempt to analyze all types of Greek metre into short "feet" (e.g., iamb — —, as in Latin comedy, instead of — — — — —). This system is still found in out-of-date metrical works. His terminology (e.g., names of feet) has been adopted even in English metrical theory, to which it is ill-suited. Since about 1800 classical metricians have discarded much of Hephaestion's theory and terminology, but misleading terminology is still in use, and there are few reliable modern works.

PROSPECTING: see MINE PROSPECTING AND DEVELOPMENT.

PROSPER, SAINT, OF AQUITAINE (PROSPER TIRO) (c. 390- c. 463), theologian, important because of his influence in making moderate Augustinianism normative in the Roman Catholic Church's teaching on grace, was born in Aquitaine (South Gaul) in the last years of the 4th century, and moved to Marseilles sometime before 428. There he lived as a monk, having left his wife, whom he encouraged to adopt an analogous way of life. He was an acute theologian and championed St. Augustine's (q.v.) doctrine on grace and predestination in opposition to the contemporary Gallic ascetics whose anti-Augustinian views are now called Semi-Pelagianism (q.v.). In 428 Prosper wrote an appeal to Augustine for help, and he and his colleague Hilary (a figure otherwise unknown) received a bipartite opus shortly before Augustine's death. As the Semi-Pelagians published their attacks on Augustine, Prosper single-handedly rose to his defense. Against the most revered monk of the era, John Cassian, he wrote *De gratia et libero arbitrio contra Collatorem*. Against the respected Vincent of Lérins he wrote *Responsiones ad obiectiones Vincentianas*. In opposition to the general Gallic attack on Augustine, he wrote *Ad obiectiones Gallorum calumniantium*. The battle in Gaul was too one-sided, and after Augustine's death, Prosper went to Rome in 431 to enlist Pope Celestine I for the Augustinian cause. The pope wrote a letter to Gaul praising Augustine without being precise about what was being praised. (The propositions, *Indiculus Coelestini*, which later became attached to the letter, were most

probably Prosper's own formulation of Augustinianism.) After the visit to Rome in 431, Prosper returned to Gaul, but by 435 he left it definitively, establishing himself at Rome as papal secretary to Leo the Great. Before his death he composed a collection of Augustinian propositions called *Liber sententiarum Sancti Augustini* which was used in the decrees of the second Council of Orange (529). Prosper also wrote an important *Chronicle*, though it is not altogether reliable. The identification of Prosper with a later bishop of Reggio is untenable. His liturgical feast day is June 25.

O'Donnell, C.S.B., "Grace and Free Will" in *Fathers of the Church*, vol. vii (1949); P. de Letter, S.J., "The Call of All Nations," in *Ancient Christian Writers*, vol. xiv (1952). See also L. Valentin, *Saint Prosper d'Aquitaine* (1900). (G. WL.)

PROSTATE, a gland in the male that surrounds the neck of the bladder and the urethra. See **REPRODUCTIVE SYSTEM: Anatomy and Physiology: Male**; **URINARY SYSTEM**.

PROSTEJOV, a manufacturing and market town of North Moravia, Czech., lies on the south bank of the Romza River, a tributary of the Morava, 50 mi. (80 km.) NE of Brno by rail. Pop. (1961) 33,807. It is at the northwestern extremity of the Hana farming region, and owes its industrial and trading growth both to the extreme fertility of the Hana land and to the development of modern textile production from medieval crafts.

The old core of Prostejov contains remains of the former Jewish ghetto and a 16th-century castle. It was once a well-known centre of the Moravian Brethren. The surrounding, newer quarters contain the largest clothing factory (Jiri Wolker plant) of Czechoslovakia, which is a combination of more than 60 small enterprises. Other industries (based on agriculture) include brewing and distilling, milling and sugar refining, and also the manufacture of agricultural machinery. (H. G. S.)

PROSTHETICS is the branch of surgery having to do with artificial organs and parts (prostheses). Though by definition a prosthesis is any artificial organ or part replacing a missing natural one, this article is devoted exclusively to those most commonly called "prostheses"; i.e., those replacing lost arms or legs. Other prosthetic devices are discussed in **PROSTHODONTICS** (dental prosthetics) and the related article **TEETH, ARTIFICIAL**; and **EYE, HUMAN: Artificial Eyes**. Devices that assume or augment the functions of diseased organs are discussed in **ARTIFICIAL ORGANS** (lung, heart, and kidney); **EYEGLASSES**; and **HEARING AID**. Braces, which give support or stability to a limb or joint, are not replacement parts, hence are not considered prostheses; instead, they are known as orthotic ("straightening") devices.

History.—Lower-extremity prostheses were used as early as 600 to 500 B.C., but the origin of prosthetics as a science is attributed to the 16th-century French surgeon Ambroise Paré. Later workers developed upper-extremity replacements, including metal hands made either in one piece or with movable parts. The solid metal hand of the 16th and 17th centuries later gave way in great measure to a single hook or a leather-covered, nonfunctioning hand attached to the forearm by a leather or wooden shell. Improvement in the design of prostheses and increased acceptance of their use have paralleled the various major wars. New lightweight materials and better mechanical joints were introduced following World Wars I and II.

The desire to walk causes leg amputees to accept lower-extremity prostheses readily, even if they are not perfectly constructed or fitted. Thus such devices for lost feet and legs are far more advanced than those for hands and arms.

Reasons for Prostheses.—The chief reason for employment of prosthetic devices is surgical removal, or amputation, of a part. Amputation may be a lifesaving measure following severe injuries or crushing fractures; and many diseases affecting muscles or bones require amputation as the only possible treatment. Amputation sometimes is resorted to in cases of severe deformity of an extremity, from either a congenital abnormality or a disease such as poliomyelitis; in these cases the extremity may be not only useless but grotesquely shaped, and amputation and subsequent fitting of a prosthesis gives better function with better appearance. The general rule in all amputation surgery with a view toward the fitting of a prosthesis is to save all the limb length possible.

A less common use of prostheses is to replace arms or legs absent or stunted at birth (phocomelia and similar anomalies; see **MONSTER**).

Wearing a Prosthesis.—The earlier a prosthesis can be provided for an amputee the sooner he will learn its use and the more consistently he will wear it. If he learns to use the amputation stump or to compensate for his loss in some other way, he is likely to reject the prosthesis.

The person born without a limb presents a different problem. Since he never had an arm or leg, he does not have the memory of what he could do with the extremity to contrast with what he can now do with the prosthesis. This problem is best overcome by providing the prosthesis at the earliest practical age.

The child given a prosthesis before the age of 6 is a better prosthetic wearer than is one to whom the prosthesis is given later in life. A lower-extremity prosthesis should be fitted when the child shows the normal tendency to attempt standing—somewhere between 6 and 15 months of age. Upper-extremity prostheses, being more complicated and requiring more mechanical coordination, are fitted later, the below-elbow type at 18 to 24 months and the above-elbow type at 3 or 4 years.

Lower-Extremity Prostheses.—The leg prosthesis is basically made of willow wood. In the below-knee type the wooden socket is fashioned to fit the stump perfectly. A wood-and-metal foot is attached by a joint so that there is some ankle and toe motion. At the upper end of the prosthesis are metal hinges so that the knee will bend. Attached to the knee hinges is a thigh piece made of heavy leather; this laces in the front and fits the thigh very snugly, so that part of the wearer's weight is supported by the thigh corset and the remainder is supported by the bone below the knee in direct contact with the prosthesis.

The above-knee prosthesis consists of two willow sockets, the below-knee and foot portions being similar to the below-knee type. The above-knee portion is hollowed out to fit the stump, and extends to the pelvis, which bears the body weight. The above-knee and below-knee portions are connected by a mechanical knee joint. The wearer does not have direct control of the knee joint, hence walking requires considerable skill. There are two main types of above-knee prostheses: (1) the prosthesis held on by means of a belt around the pelvis or suspended from the shoulder

FROM "ORTHOPAEDIC APPLIANCE ATLAS," VOLUME 2

APRIL-SIERRA 44C ARTIFICIAL HAND, SHOWN WITHOUT COSMETIC GLOVE WHICH MUST BE USED

Spring and cam mechanism inside the hand (outaway), operated by a control cable, moves the index and middle fingers toward the thumb. The mechanism is mounted on a steel frame and covered with aluminum. The first two fingers are made of stainless steel and have pads of felt on their inner surfaces. The third and fourth fingers, made of foam rubber, serve only to fill out the glove.

by straps, and (2) the prosthesis kept in contact with the leg stump by suction, the belt and shoulder straps being eliminated.

The more complicated prosthesis used in cases of amputation through the hip joint or half of the pelvis usually consists of a plastic socket, in which the person virtually sits; a mechanical hip joint of metal; and a leather, plastic, or wooden thigh piece with the mechanical knee, shin portion, and foot as described above.

Upper-Extremity Prostheses.—A great advance in fabrication of functional upper-extremity prostheses followed World War II. Arm prostheses came to be made of plastic, frequently reinforced with glass fibre.

The below-elbow prosthesis consists of a single plastic shell and a metal wrist joint to which is attached a terminal device, either a hook or a hand. The person wears a shoulder harness made of webbing, from which a steel cable extends to the terminal device. When the person shrugs the shoulder, thus tightening the cable, the terminal device opens and closes. In certain cases the biceps muscle may be attached to the prosthesis by a surgical operation known as cineplasty. This procedure dispenses with the shoulder harness and allows finer control of the terminal device.

The above-elbow prosthesis has, in addition to the forearm shell, an upper-arm plastic shell and a mechanical, locking elbow joint. This complicates its use, inasmuch as there must be one cable control for the terminal device and another control to lock and unlock the elbow.

The most complicated upper-extremity prosthesis, that used in cases of amputation through the shoulder, includes a plastic shoulder cap extending over the chest and back. Usually no shoulder rotation is possible, but the mechanical elbow and terminal device function as in other arm prostheses.

A metal hook that opens and closes as two fingers is the most commonly used terminal device and the most efficient, though of somewhat formidable appearance. After World War II the APRL (U.S. Army Prosthetic Research Laboratory) hand was developed. This is a metal mechanical hand covered by a rubber glove of a colour similar to that of the patient's remaining hand.

PROSTHODONTICS is the branch of dentistry that deals with the artificial replacement (prosthesis) of natural teeth and associated tissues for the restoration or maintenance of function, appearance, comfort and health. Prosthodontics is divided as follows: (1) fixed partial denture prosthesis; (2) removable partial denture prosthesis; (3) complete denture prosthesis; and (4) maxillofacial (jaw and face) prosthesis.

History.—The earliest prosthodontic devices were banded bridges made by the Etruscans and wired restorations constructed by the Phoenicians. In early history human teeth, animal teeth or teeth carved from wood or ivory were substituted for natural teeth, and complete dentures for either the upper or the lower jaw were sometimes carved from one solid piece of wood or ivory. Early prosthetic appliances were crude, awkward and almost useless in mastication; they were unhygienic and unsightly.

Porcelain teeth were introduced during the latter part of the 18th century, and in the 20th plastic teeth came into use. Continued research with both these materials has produced lifelike imitations of teeth to match the large number of variations found in the colours and forms of natural teeth. Gold alloys and chrome alloys possessing the correct amount of rigidity, yet with sufficient flexibility to be suitable for clasps, bars, bases and attachments, have been highly developed. Methods and techniques of manipulating the various materials, and specialized instruments and equipment used in the construction of prosthetic restorations, have kept pace. Crowns, bridges, and partial or complete dentures (see below), as well as the several maxillofacial replacements, can be made so realistic in appearance and so functional that they almost defy detection.

Fixed Partial Denture Prosthesis.—This includes the design, construction and maintenance of dental restorations such as crowns and bridges that cannot be readily removed from the mouth by the wearer or dentist. These types of restorations are rigidly fixed to the natural teeth, which furnish support to them, and may

be made of porcelain, plastic or metal. A crown is a replacement used to restore the natural form of an impaired tooth that cannot be preserved by an inlay or other type of restoration. A bridge, as the name implies, consists of a span of one or more artificial teeth, with abutment attachments that are cemented to the adjacent natural teeth in the mouth.

Removable Partial Denture Prosthesis.—This includes the construction and maintenance of dental restorations so designed that they can be removed at will by the wearer or dentist. A removable partial denture consists of a base, constructed of plastic material or metal, or a combination of the two, which accurately fits the mouth ridges and tissues and supports the artificial replacement teeth in proper alignment. It is held in position in the mouth by flexible metal bands or clasps encircling adjacent natural teeth, or by other means of attachment to the teeth.

Complete Denture Prosthesis.—This involves the artificial replacement of all the natural teeth and associated tissues, in either the upper or the lower jaw or in both. In this type of prosthodontics, restoration of the functions of mastication, speech and appearance is of the greatest importance. Establishing and maintaining these functions by means of artificial dentures is accomplished by attaching porcelain or plastic teeth to bases (plastic material, metal or a combination of the two) that have been accurately adapted to the soft tissues of the mouth.

Maxillofacial Prosthesis.—This deals with the artificial replacement of tissues in cleft palates and other oral abnormalities. Cleft palates are abnormal openings of varied size and form in the roof of the mouth, usually of congenital origin. Mastication, swallowing and speech are seriously impaired by this type of abnormality. Closure of the opening by inserting a removable prosthesis can greatly improve these functions. Maxillofacial prosthesis has also come to include artificial restorations of some extraoral conditions of the face and head, resulting from injury, disease, or congenital factors.

Prosthodontics as a Specialty.—In the United States, dentists with the necessary training and experience to deal with all types of dental prostheses are, after examination by the American Board of Prosthodontics (authorized in 1948 by the American Dental Association), granted certification by that board, designating them as specialists in prosthodontics. Special training in prosthodontics, in addition to that taught at the undergraduate level, can be obtained in many dental schools. See also TEETH, ARTIFICIAL.

(B. L. H.)

PROSTITUTION. Prostitution as the term is generally employed by sociologists, social workers, and the courts refers to the promiscuous bartering of sex favours for monetary considerations (either cash or gifts) without any emotional attachment between the partners. This definition is employed throughout the article unless the context indicates otherwise. Legal definitions vary, however, and in some jurisdictions the term prostitution subsumes all types of sexual promiscuity. Usually prostitutes are female although male prostitutes exist. Most of these are homosexual. Prostitution is as old as civilization and appears to be closely related to urban life and mobile populations. Among primitive people prostitution is virtually unknown although promiscuity before marriage and polygamy may be tolerated. In all civilized countries legal restrictions varying in severity have been enacted to control prostitution. Such restrictions have been made partly in the attempt to prevent the spread of venereal disease (*q.v.*). In the United States prostitution is an offense subject to arrest and punishment. In many countries there is a certain degree of tolerance of prostitution although there is simultaneously an attempt to restrict it. In general there is common agreement that prostitution is degrading to human dignity and especially to women. For this reason the Economic and Social Council of the United Nations has adopted a Convention urging the abolition of prostitution and the "traffic in persons" throughout the world.

HISTORY

Primitive Peoples and the Ancient World.—Studies in social anthropology do not concern themselves very much with

prostitution. Among primitive people the existence of polygamy and the early age of marriage conceal or even obviate promiscuity for hire. If promiscuity were alone the test then the practice of the utmost sexual freedom would be within the definition. From studies of existing primitive communities it would appear that sexual freedom and strict observation of the matrimonial norm vary considerably. Margaret Mead in her book *Male and Female* (1949) does indeed refer to the prostitution of slaves captured in war by the Manus tribe in Melanesia: this is done in order to make money by a tribe described as "efficient puritans" among whom there is a general devaluation of sex (see also MARRIAGE, PRIMITIVE).

In rather more advanced communities, the prostitution of unmarried girls seems to have been a common practice and the reasons for it are various: namely, as a puberty ceremony (that is, a sacrifice of virginity); as a puberty rite to earn a dowry; and as religious prostitution in the service of a goddess.

In Babylon, in Cyprus, among the Phoenicians, and in many parts of western Asia it is recorded that women prostituted themselves as a religious duty at the sanctuary of a goddess, whose name varied with the locality. Sir James Frazer in *The Golden Bough* observed that, despite the change of name, her type remained constant, namely, the great Mother Goddess of western Asia (see GREAT MOTHER OF THE GODS; APHRODITE; ASTARTE). The Babylonian custom, as recorded by Herodotus, required every woman, rich or poor, to sit in the temple of Ishtar and have intercourse with a stranger, who signified his choice by throwing a silver coin of no matter how small value into her lap. The woman had then to accept the coin and have intercourse with the stranger. Once the rite had been observed the woman was absolved from her obligations to the goddess; and then, according to Herodotus, money would in no case purchase her. The customs in Cyprus and elsewhere seem to have followed a similar course, but it was more usual for prostitutes to be in permanent service to a temple.

Whatever the motive for these customs, whether as a sacrifice of virginity, to earn a dowry or as a religious service, the practice was a solemn religious duty. Frazer suggested that these religious duties were closely knit with the reproductive energies of nature as a whole and represented a survival of communal fertility rights. (See also ADAM AND EVE; CIBEIRI; FOLK DANCE.)

Attempts have been made to trace the origin of religious prostitution to the purely secular and precautionary practice of destroying the bride's virginity before her marriage. There is no doubt that, in some communities, there is a fear that a man will be endangered by some peril attaching to virginity. It is certain that defloration of virgins has played and still does play an important role; but its significance is far from clear. This custom is thought ultimately to have developed into the *jus primae noctis* vested in the local lord or priest. The rites accompanying the sacrifice of virginity in a woman are paralleled perhaps by the puberty rites observed in primitive communities in relation to youths as recorded, for example, by Theodor Reik in *Probleme der Religionspsychologie* (1919).

Among the Jews, who stood apart from the surrounding peoples, the object of the Mosaic law was clearly to preserve the purity of the race and the religion. Prostitution in itself was not forbidden, but it was to be confined to foreign women. Jewish fathers were forbidden to turn their daughters into prostitutes (Lev. 19, 29), and the daughters of Israel were forbidden to become prostitutes (Deut. 23, 17), but no penalty was attached to disobedience, except in the case of a priest's daughter, who was to be burned (Lev. 21, 9). There is abundant evidence in the Old Testament that prostitution prevailed extensively in Palestine, even in the earlier and more puritan days. Harlots were forbidden Jerusalem and places of worship; they infested the waysides, and there is some evidence of a distinctive dress or bearing, which was a marked feature of the trade among the Greeks and Romans.

The earning of a dowry is also shown by ancient customs to have been a motive for prostitution. The girls of Lydia regularly prostituted themselves to earn a dowry, and the Palau (Pelew)

Islanders systematically prostituted their daughters for hire and derived an income therefrom, perhaps with the intention likewise of providing them with a dowry. A similar custom prevailed as late as the early years of the 20th century among the Ouled Naïl of Algeria: the girls of this tribe would go to the larger towns (e.g., Biskra) as dancing girls and earn money by prostitution; then they would return home and marry; and the more money they had acquired, the more desirable they were considered as wives. While it may be that this motive of earning a dowry had itself originally some religious rather than economic purpose, it is clear that in later times the economic aspect featured much more largely.

Superficially at least, then, prostitution was in many countries once connected with religious worship; and it cannot be doubted that the money paid to the women in the temples came in the course of time to find its way into the priests' coffers. An example is provided by the huge temple of Aphrodite in Corinth, where there was a large staff of prostitutes in attendance to accommodate sailors frequenting the port. It may therefore be suggested that the advent of the secular brothel did not take place until the system that regulated prostitution in accordance with religious rites had broken down, while the demand for the prostitute's services continued.

The regulations of Solon in Athens were designed to preserve public order and decency. He established houses of prostitution (*dicteria*), which were a state monopoly and confined to certain quarters. The *dicteriaes* were forbidden the superior parts of the town and were placed under various disabilities: they were compelled to wear a distinctive dress and, far from being connected with religion, were not allowed to take part in religious services. These laws do not seem to have been carried out at all effectually and were presently relaxed; but it is clear that, as time went on, the Athenian authorities experienced the difficulties encountered by modern administrations in carrying out state regulation. On the other hand the *hetærae*, independent courtesans of the most expensive class, had an enviable place in Greek society where their intellectual as well as their physical attainments were widely respected (see ASPASIA; PHRYNE; LAIS).

In ancient Rome the moral tone seems to have been of a very different stamp: the Romans combined a pride of race like that of the Jews with a regard for public decency like that of the Athenians and had also a standard of austerity all their own. In early times female virtue was highly honoured and strenuously preserved by the Romans (e.g., in their institution of the Vestal virgins): to frequent the company of prostitutes was accordingly considered disgraceful—though we may cite the opinion, attributed by Horace (*Satires*, i, 2) to the conservative Cato, that it was right (*aequum*) for young men driven by lust to go to brothels rather than molest other men's wives. The Roman system of regulation was especially severe: prostitutes were placed under stringent control, were required to register with the police, had to wear distinctive dress and to dye their hair or wear yellow wigs, and were subject to various civil disabilities. The state's taxation of prostitutes, which had been transmitted from the Roman republican to the imperial period and had been further regulated by Caligula, was however partly renounced in the Christian 4th century by Theodosius (on the representations of Florentius, a wealthy patrician, who offered to make good the loss of revenue out of his own pocket) and was finally abolished in the 5th by Anastasius I, and the old registers were destroyed. Then some of the civil disabilities of prostitutes were removed by Justinian in the 6th century. Edward Gibbon attributes Justinian's action to his desire to marry Theodora, whose life had been notorious, but though no doubt she influenced him in the matter, Gibbon admits her virtue after marriage and gives her credit for "the most benevolent institution" of Justinian's reign, the rescue home for fallen women in Constantinople. This, though it did not succeed marks a turning point in the treatment of a class which had never met with public sympathy before.

The Middle Ages.—In the Middle Ages prostitution was tolerated, the caprice of the passions being recognized as a necessary evil. Nevertheless, efforts were made to check it, or at least

to keep it within reasonable bounds. Christianity put an increasing emphasis on chastity and on the sanctity of the marriage vows, though the observation of the monogamous status of marriage was accepted only gradually. St. Augustine took the view that a plurality of wives, as distinct from a plurality of husbands, is not contrary to the nature of marriage: "*plures enim feminae ab uno viro fetari possunt, una vero a pluribus non potest*" ("for more women than one can be made pregnant by one man, whereas one woman cannot [at the same time] be made so by more men than one": *De Bono Conjugali*). He and others following him regarded this natural law as modified at a later date by the institution of monogamy as a discipline imposed by the divine authority on Christians. In furtherance of the more humane Christian doctrines, attempts were made to better the lot of prostitutes and to induce them to reform. The church became exceedingly active in prevention and rescue work and was assisted by a devout and zealous laity; rescue missions were organized, convents were founded everywhere for the reception of penitents, and dowries were subscribed to procure them husbands. Fulk of Neuilly was a conspicuous figure in this work, holding missions, preaching and collecting large sums for marriage dowries. Pope Innocent III pronounced it a praiseworthy act to marry a prostitute; and Gregory IX wrote to Germany that brothel-keepers were not to prevent prostitutes from attending missions and that clergy and laity who drew profit from prostitution were banned. "Urge bachelors," he wrote, "to marry repentant girls, or induce the latter to enter the cloister."

Meanwhile, apart from the church's doctrine, the feudal order of society had its own influence on the medieval attitude toward relations between the sexes. In feudal times, when the possession of land was the criterion of wealth and status, marriage among the greater landowners, though subject to the laws of the church, was most often primarily a political matter, to be arranged by open bargaining between overlord and overlord or between the heads of the two families concerned; love, then, did not enter into the question (indeed it would appear that love, as understood in the 20th century, is a comparatively recent development in human life). Women of the highest rank in feudal society were thus treated to a large extent as salable chattels; and their status cannot have been without its reflection in the contemporary attitude toward women in general. On the other hand, the feudal service due from a vassal to his lord provided the model for the lover's service to his lady according to the code of chivalrous or courtly love which the troubadours conceived and formulated in the 11th, 12th, and 13th centuries. This new idealization of love was clearly hard to reconcile with indiscriminate recourse to prostitutes; but insofar as courtly love was regarded as existing not between husband and wife but extramaritally (a "court of love" is said in fact to have pronounced love between husband and wife to be impossible), it must have contributed to the divergence from Christian standards that made prostitution acceptable to those at least who were not chivalrously in love.

In an era when almost the whole population came to be divided into guilds, prostitutes would appear to have formed a regular guild of their own; at the very least, they seem to have had a recognized function in social life. A general distinction, however, can be made between the resident prostitutes, who lived in "bordels," and the itinerant ones, who were either vagrant or else informally attached, as camp followers, to the temporal or spiritual armies that swept to and fro across Europe, now waging wars, now fulfilling vows. Prostitution indeed was not merely tolerated but protected, licensed and regulated by law, and constituted in many places a source of public revenue.

In France prostitutes were distinguished by a badge and forbidden to wear jewels and fine stuffs and to frequent certain parts of the towns. Public brothels on a large scale were established at Toulouse, Avignon and Montpellier; at Toulouse the profits were shared between the city and the university; at Montpellier and Avignon the trade was a municipal monopoly and farmed out to individuals; at Avignon, where the establishment was kept up during the whole period of the popes' residence, the inmates were subjected to a weekly examination. In some parts of France

prostitutes paid a tax to the seigneur. In Germany, public *Frauenhäuser*, similar to the French brothels, existed in many places. In Italy and also in Spain the system appears to have been very much the same: in Bologna prostitutes had to wear a distinctive dress, in Venice they were forbidden to frequent the wineshop, and in Ravenna they were compelled to leave a neighbourhood on the complaint of other residents. In Naples, moreover, a court of prostitutes was established, having jurisdiction over everything connected with prostitution. It led to great abuses and was reformed in 1589 and abolished about a century later.

In England the most notorious "bordels" or "stews" were those which occupied a row of buildings in the Borough (Southwark) near London Bridge, originally licensed by the bishops of Winchester (according to John Noorthouck) and subsequently sanctioned by Parliament; John Stow quotes the regulations enacted in the year 1161, during the reign of Henry II. These bordels were closed in 1506 but reopened until 1546, when they were abolished by Henry VIII. In London also we get an early regulation directed against the spread of venereal disease: the act of 1161 forbade the bordel-keepers to have women suffering from the "perilous infirmity of burning"; and by an order of 1430 they were forbidden to admit men suffering from an *infirmity nefanda*. As in other countries, regulations respecting the dress of prostitutes were made in England: by a royal proclamation of Edward I, the wearing of miniver (a kind of fur) or sendal (a kind of thin silk) on hoods and dresses was forbidden to prostitutes.

Prostitution and Religious Reforms.—According to Paul LaCroix in his *History of Prostitution*, scandals associated with the clergy and the brothel at Avignon, and with other brothels elsewhere, were apparently influential in inducing large numbers of persons to join anticlerical and puritanical groups in the 11th century and the Catharist sects in the 12th and 13th centuries. The Cathars had important doctrinal differences with the church (see CATHARI). But some of their popular appeal, and that of other heretical sects, lay in their objection to widespread corruption among the clergy.

In the meantime, the spread of humanist ideas since the medieval beginnings of the Renaissance was bound to raise the status of women; and the rise of monarchical absolutism in the 16th century meant the end of the old feudal order, which, as we have seen, tended to keep them in subjection. The Reformation brought a radical change in sexual morality: not only was the former insistence on celibacy, which had deprived the many thousands of clerks of any licit outlet for incontinence, abandoned in many countries, but also, to balance this liberalization of marriage, the Christian condemnation of extramarital licence was emphasized. The Reformers' stricter attitude to unchastity was moreover echoed by the Catholics of the Counter-Reformation, conscious as they were of the harm that had been done to the church by its toleration of more licentious conduct. In this climate of opinion the many statutes enacted throughout Europe to control the prostitutes were apparently enforced to some effect: for example, in Strasbourg, where the cathedral seems formerly to have been a common place of resort for soliciting and the open activity of the numerous prostitutes a scandal, there were by 1536 only two brothels, and four years later public prostitution seems to have been effectually suppressed. In England under the Commonwealth, fornication was made a felony upon a second conviction, punishable by death, without benefit of clergy (1650); but this statute was repealed at the Restoration.

The reforms of the 15th and 16th centuries coincided with and were given added impetus by a virulent outbreak of syphilis. It was labeled a new disease and known as the pox, the bad pox, and the great pox. It was said to have come from the New World, carried by Columbus' sailors, and was called the Spanish disease, the French disease, the English disease, etc. Because of fear of the disease, prostitutes often were subject to severe punishment.

From the legal point of view in England, meanwhile, the type of offense with which prostitutes might ordinarily be charged began to pass, after 1640, from the jurisdiction of the ecclesiastical courts to that of the common law. Prostitution itself was not a crime and public nuisance became the basis of prosecution, a

development of this being the misdemeanour which is committed by anyone who does any grossly indecent act in any open or public place in the presence of more than one person. The liberty of the subject was jealously guarded, and intervention was not permitted except in the case of a disturbance such as would have necessitated action even in the most respectable mansion in the land. Brothels, however, were included among the establishments against which the Disorderly Houses Act of 1751 was aimed.

The Industrial Revolution.—After the creation of the police force in the 19th century, the control of prostitution and its offshoots took on a more ordered appearance. Almost concurrently, however, the question of prostitution began to assume a problematic form as the Industrial Revolution set its mark upon the world: mass movements took place away from the country into the towns, where people were crowded together under wretched housing conditions, their leisure occupations restricted and their everyday work monotonous and emotionally unsatisfying.

Henry Mayhew, in an appendix to his *London Labour and the London Poor* (1861), divided prostitutes into three classes: first, those women who were kept by men of independent means; second, those women who lived in apartments and maintained themselves by their trade; and third, those who dwelt in brothels. There were in addition amateurs who took money but only practised prostitution as a sideline to their daily occupation. The squalor of the slums combined with addiction to drink induced a terrible apathy and recklessness in these women. The all-night operation of public houses where men and women could meet was another aspect of the trade. Yet even under these conditions the spread of enlightenment and education in the shape of an energetic police force and better parochial management was making itself felt.

The religious revivalist movements, such as the Evangelical movement and the Salvation Army, during the latter half of the 19th century, do not, from all accounts, seem to have had a very profound effect on the poorer classes as a whole. The general report seems to have indicated indifference to religion. This is brought out in relation to London by Charles Booth in *Life and Labour of the People in London* (new ed., 1902-03). Though this author deals with the years 1890 to 1900, he quotes ministers of religion who had been in their respective parishes for 30 years or more.

On the other hand, the rescue work undertaken by the various missions established in poverty-stricken areas was remarkable. The success achieved was mostly confined to the women who had recently joined the ranks of the prostitutes; many of these were promptly picked out and in some way rehabilitated. The workers effected this change through their personal influence, though they themselves were inspired by deep religious feeling. According to the reports, they found that the favourable time for persuading a prostitute to change her way of life was immediately after the birth of the first child; with this may be compared the experience of later social investigators in the U.S.S.R., who found that one of the most opportune times for reclamation was during the treatment for venereal disease.

LEGISLATION AND REGULATION

The law and morals are not of course identical, and in all countries the problem of enforcing legislation so closely related to variable moral codes of behaviour is fraught with difficulties: as soon as the law enters the sphere of morals, both its interpretation and its execution may be called in question as unjust or indeed immoral, at least by some members of the community. In Great Britain, for example, the Contagious Diseases Prevention acts of 1864, 1866, and 1869, which introduced a measure of state regulation and inspection of prostitutes, had to be suspended in 1883 and repealed in 1886 as a result of the campaign initiated against them in 1869 by Josephine Elizabeth Butler (*q.v.*), leader of the international movement to abolish state regulation (and therefore acceptance) of prostitution. There remained little that the law could do in relation to the prostitutes themselves except to see that the police maintained a certain standard of order.

In some countries, on the other hand, special "morals police"

were instituted, with more power than the English "vice squad" and with the function, among others, of observing the registered prostitutes and watching for any who were unregistered; but the arbitrary power that these "morals police" could exercise caused considerable misgiving. Yet again, some countries, for instance Belgium, favoured the employment of women police to deal specifically with prostitutes. It may be stated, however, that the laws controlling prostitution and kindred offenses in the different countries of the world are very similar once the fundamental distinction has been made between those of countries in which houses of prostitution have been abolished by law and those of countries which permit brothels and require prostitutes to be registered (of course, some countries cannot be classified in this way).

In Great Britain, legislation, apart from laws dealing with soliciting and offenses against decency in public places, is directed not at the prostitute or her client but against those third parties—brothel-keepers, procurers, pimps—who find her commerce so profitable and so easy to exploit. Thus while prostitution itself still is not a penal offense, a series of enactments were developed during the 19th century to prevent procurement, to close brothels (defined as premises used by at least two women for purposes of prostitution), to penalize landlords who rented their buildings for such purposes, and to prohibit a man's living on a prostitute's earnings. The Street Offenses Act of 1959, following recommendations of the Wolfenden Report (the report of the Departmental Committee on Homosexual Offences and Prostitution), for the first time prohibited all street solicitation and loitering by prostitutes, with increasing fines for repeated offenses. The Act also raised the fines for permitting solicitation in refreshment houses and increased maximum penalties for procuring and for living on the earnings of prostitution.

The difficulties that attend the abolition of houses of prostitution in a country where they have been long established are illustrated by the course of events in France. In 1946, state registration was ended and the *maisons de tolérance* were closed; then a subsequent law, in the same year, established a *fichier sanitaire* for all prostitutes and regulated their registration for purposes of hygiene (*i.e.*, for contact-tracing and the treatment of venereal disease); and a further enactment (1948) seemed to make prostitutes subject to examination even before their occupation was proved, the effect being practically a return to the regime of state registration.

The law of 1946 had indeed resulted in the closing of the brothels in France, but little was done for the rehabilitation of their inmates, and it soon appeared that the latter were pursuing their old trade under worse conditions than before. Marthe Richard, a national heroine of World Wars I and II, who had been among the first to urge the closing of brothels in Paris and indeed was held to be primarily responsible for the enactment of the law, showed that she had changed her mind about the rightness of the measure in her book, *L'Appel des sexes* (1951). To make a compromise between the abolitionists and those who wanted to repeal the law of 1946 it was proposed that brothels should be allowed in the neighbourhood of army camps at least.

In the United States, houses of prostitution are illegal in most states, as also is procuring; and the majority of the states penalize soliciting and living on the earnings of prostitution. The federal Mann Act (the White-Slave Traffic Act; 1910) prohibits the transporting of a woman across state lines for immoral purposes, and interstate travel or transportation in aid of illegal business activities, including prostitution, was banned by anti-racketeering laws passed in 1961. For an analysis of the laws controlling prostitution and kindred offenses in the various states see Gerhard Mueller, *Legal Regulation of Sexual Conduct* (1961). It may here be remarked that the attempt to "clean up" Chicago in 1929 provided a notable demonstration of the danger of driving prostitution underground, where it can become more vicious and disruptive to society than when it is allowed to exist, to some extent, openly (see Walter C. Reckless, *Vice in Chicago*, 1935). Such a development is to be expected on the closing of brothels when at the same time no fundamental alteration of the social

pattern is effected: the removal of the controls exercised by the brothel system clears the way for a "vice racket" in which both prostitute and client are exploited by third parties. In the United States strictly criminal organizations largely took control of prostitution, managing it on a national or regional basis (see *GANGSTER*).

With the closing-down or repression of the more flamboyant operations of streetwalkers and houses of prostitution, other categories emerged. One was the bar girl, or b-girl, employed to entertain men customers of a bar, tavern, or nightclub and induce them to spend money, often by offering to perform lewd or indecent acts or to engage in prostitution. The b-girl is in the tradition of the dance-hall "hostess" of, for example, the cow towns and mining towns of the American west. And a new upper class among prostitutes emerged—the call girl who, while working for a madam or panderer, meets her customers by appointment, usually made by telephone call, at his hotel room or apartment, or at her apartment. She may be quite selective in her choice of customers, at least limiting her favours to men who are willing and able to pay high fees. Other categories, by no means new, include young women who successfully pretend to engage in other, respectable occupations, such as office worker, beautician, entertainer, photographers' model, etc., and others who actually do engage in such occupations but also engage in prostitution when opportunity arises.

By the second half of the 20th century, then, legislators might be confronted with the dilemma of choosing between an abolitionist policy, active support for which was forthcoming from many quarters both religious and secular, and a policy of regulation, arguments for which could be drawn from sad experience. There was thus little cause for surprise whichever policy was adopted: in December 1954, for instance, the Argentine government, despite the contemporary world's general tendency toward abolitionism and in the face of the particular abolitionism of the Roman Catholic Church, authorized the reopening of brothels, on the ground that their suppression in 1937 had led to an increase of venereal disease, sexual perversion, and crime; and less than a month later, in January 1955, a majority in the Italian senate, disregarding the cautionary spectacle that France had just provided, approved a bill for abolition.

In the U.S.S.R., the bold claim was made in the 1930s and 1940s that no prostitution and no brothels or trafficking in the streets existed any longer. The legislation and administrative orders promulgated indicated that the problem had been treated very seriously. Before the Revolution, prostitution existed on a very large scale in Russia. The desire of the revolutionaries to abolish it would seem perhaps to emanate from the urge toward female emancipation and equality of the sexes. With regard to prostitution, the Soviet authorities repeatedly emphasized that the war against it should on no account degenerate into a war against prostitutes. It was maintained that the disappearance of prostitution in the U.S.S.R. was due in effect to the changing of the cultural patterns in Russian and Soviet society. The exact meaning of this asseveration is difficult to assess: the U.S.S.R. is a very large country comprising a number of republics, each with its separate codes of law and in a varying stage of development; and in some of these republics tribal customs, in particular those connected with child marriage and with the bride price, would seem to have survived for a long time. Occasional reports of clandestine prostitution continued to appear.

After World War II other Communist countries in Europe proclaimed the abolition of prostitution. (T. E. J.; X.)

International Concern.—Prostitution has been widespread and widely accepted in Asia with casual sexual relations between both married and unmarried men and prostitutes regarded as a matter of course. Until recent times it was almost the only occupation open to dependent and unattached women. That prostitution was long accepted as a way of life throughout the Middle East and the Far East was held to be related to the inferior position of females. The surge of rising aspirations in the nations of Asia after World War II encompassed strong movements to improve the status of women. These found support in the United Nations

in the Universal Declaration of Human Rights, in the Economic and Social Council's efforts to combat and reduce prostitution as incompatible with the dignity and worth of a human being, and in its Convention for the Suppression of the Traffic in Persons and Exploitation of the Prostitution of Others.

In connection with its attempts to abolish prostitution as a practice imposing indignities on human beings, the UN made a number of surveys in member countries. Surveys of countries in Asia and the Far East covered Burma, Ceylon, India, Indonesia, Japan, the Philippines, and Thailand. With the exception of Thailand all of these nations had adopted laws before 1960 either to abolish or to prohibit prostitution. In Thailand, prostitution was regulated and all prostitutes and brothels were registered. No new prostitutes were permitted a license after 1956, and no new brothels were allowed to open after 1948; the government reported it expected to abolish prostitution eventually.

Despite laws aiming to prohibit or suppress prostitution, it was found still to exist in the other countries mentioned. In Burma, Ceylon, Indonesia, and the Philippines it was basically an urban phenomenon. In India on the other hand the majority of prostitutes (66.5%) were from rural areas. In some parts of India prostitution was still associated with girls dedicated to temples, and in some communities certain girls were dedicated to prostitution, although both forms of religious prostitution were forbidden by law. In northern India many dancing girls still became prostitutes.

In Japan licensed prostitution was abolished between 1946 and 1948. Public brothels were closed and offices were set up throughout the country to rehabilitate former prostitutes and to protect girls from becoming engaged in prostitution. Many geisha girls meanwhile have been prostitutes although others do not engage in this practice (see *GEISHA*).

In the Philippines prostitution was reported in the larger cities, particularly in Manila, where the military reservations and air bases afforded many customers.

In Indonesia prostitution was reported to be common in the villages. This was blamed largely on the fact that many men, who were permitted four wives, divorced one or more wives with little concern for what happened to them: such women often resorted to prostitution. In Cambodia, brothels were permitted but were subject both to licensing and to special regulations. In Ceylon, prostitution, though it was technically an offense, was not punished as such. It could be punished, however, under the Vagrants' Ordinance. Private institutions including the Salvation Army tried to rehabilitate prostitutes and help them in securing respectable employment.

Additional surveys in Malaysia, Hong Kong, and Singapore found that measures to prevent prostitution were chiefly incumbent upon the police and immigration officials, who cooperated in checking the immigration of prostitutes and in the repatriation or deportation of prostitutes. Much preventive work was required because of the large number of Chinese refugees and case work services were developed in governmental homes and shelters and by private organizations.

Except for a small group recruited from the upper classes, economic conditions apparently have been a major factor in prostitution in all of the Asiatic and Far Eastern countries. Nevertheless, the influx of refugees into some areas, the traditionally rigid class restrictions on marriage, and exclusion of women from social life have all been important factors in promoting prostitution. In Japan and the Philippines especially, military installations have resulted in considerable demand for prostitutes despite restrictive legislation.

In mainland China the Communist government after it came into power in 1949 abolished prostitution and closed numerous brothels, converting some of the largest into youth centres. A program of reeducation for prostitutes was announced, with additional reeducation including assignment to hard labour for any backsliders.

For a detailed account of international activity for the suppression of the traffic in women and children, culminating in the assumption by the United Nations of the "functions and powers

of the League of Nations" in this respect.

The Kinsey Report.—Many attempts have been made to understand the causes of prostitution and to find ways of effectively controlling the problems it presents. Any effective program for the abolition or repression of prostitution must depend upon eliminating both the demand and the supply. This is obviously no easy matter and involves both cultural and biological considerations. Many men still believe that they must satisfy imperious sex urges and some men, as the Kinsey report (Alfred C. Kinsey, Wardell B. Pomeroy, and Clyde E. Martin, *Sexual Behavior in the Human Male*, 1948) indicates, do not find sex satisfaction in marriage. Kinsey and his associates found that "about 69% of the male white population in the United States had some experience with prostitutes," ranging from those who only visited a prostitute once or twice to those who paid regular visits. Kinsey found, however, that the percentage of men who visited prostitutes varied with their educational level. By the time they were 25 years old 74% of the 5,300 men studied who had not gone beyond grade school had visited prostitutes, in contrast to 54% of those who had gone to high school and 28% with college or university training. Many of the married men had some illicit relations but only 1.7% of their total sex outlet was with prostitutes. Even so, 40% of the married men in the high school and college level had some extramarital sex experience but only 19% of those of the grade school level admitted it. (Some of these may have understated their sexual activity.) For the unmarried, illicit experience was much higher.

On the other hand, 98% of the men who had not gone beyond the eighth grade had premarital sex relations. So, too, did 84% of those who had gone to high school and 67% of those of the college level. In general the frequency of premarital intercourse was much higher in the lower educational level. Adhering to rigid sex standards is obviously not widely observed by the male sex, at least in the United States, and complicates any program for eliminating prostitution.

The medical profession does not usually concur in any belief that sex expression is necessary for health. Nevertheless the age-old institution of prostitution is committed to satisfying sex urges and any attempt to change established habits and institutions is difficult. With sex as with many moral problems, there would seem to be no final solution since the problem is a recurring one for each individual and for each generation. Only through persistent and continuous effort can much be accomplished if any rigid standard of sex restraint is to apply. (M. A. E.)

SOCIAL, PSYCHOLOGICAL, AND PSYCHIATRIC ASPECTS

The psychiatrists and the psychoanalysts see prostitution as a much wider problem than the legislators and law-enforcement officials do: they trace its roots to emotional factors, perhaps via economic ones. The theory of instincts in classical psychology differentiates between two groups of instincts: those of self-preservation and those for the propagation of the species. One group represents the interests of the individual, the will to live; the other, the interests of the race, that is, the instinct of reproduction. Prostitution utilizes the latter to satisfy the former. Arthur Schopenhauer, one of the precursors of this school of thought, was of the opinion that in true sexual passion the advantage of the individual is subordinated to the needs of the race. (*Die Welt als Wille und Vorstellung*, 2nd ed., 1844.) In the light of this classical theory, Tibor Agoston ("Some Psychological Aspects of Prostitution: the Pseudopersonality," *International Journal of Psychoanalysis*, 1945) points out that prostitution would be a deflection of the race-preservation instinct from its original aim, inasmuch as sexual intercourse, which theoretically serves the preservation of the species, is carried out for the purpose of earning a living. The psychoanalytic observations respecting prostitution and the prostitute take into consideration factors relating to the instincts which have been classified and described. Edward Glover (*Psychopathology of Prostitution*, Institute for the Scientific Treatment of Delinquency, 1945) suggests that prostitution is connected with the lack of or deficiency in a love-object: "Promiscuity serves to deny that there was a one and only parental ob-

ject of infantile love." Agoston also believes that psychiatric experience shows that promiscuousness in prostitution implies an intentional, defiant indifference in the selection of partners: anyone at all will do; the relationship is usually marked by brevity; the partners are contemptuous of each other and remain incognito; and the incognito is fortified by fictitious tales about themselves and their families. It may follow from this "facade" theory that in fact the parties to prostitution act out a fantasy in a manner satisfactory to themselves: unable to face the reality of married life with its everyday pleasures and compromises, satisfaction is found in an imaginary relationship, which either replaces or supplements ordinary conjugal relations. The content of these fantasies may be infinitely varied, from dreams of grandeur to pleasure in degradation.

It is impossible to consider remedies or causes in relation to prostitution till more is known of the emotional problems involved or, indeed, till it is quite clear what type of person is in question. "It is absurd," says Edward Glover, "to talk at large of remedies for prostitution without establishing a reasonably exact classification of prostitutes. For that part, we ought also to have an accurate survey of allied groups, including, for example, the enthusiastic amateur, the gold-digger, the type of individual who marries for money. But if we go so far we might well consider the significance of the dowry and the marriage settlement." There are already many different classifications of the prostitutes who come before the courts in different countries; but further light can be shed on the subject by taking into consideration women who are blatantly promiscuous but should not strictly be called prostitutes as they do not ply their trade openly or for direct reward the wealthy nymphomaniac, for example, or even any women of substance who refuse to confine themselves to one man. The police do not usually concern themselves with women of this latter type, and indeed it would be difficult to show that money or its equivalent passed to them, even though there would certainly be an element of barter in the sense of gifts or pleasures. That money is a precipitating factor in many cases of true prostitution is undoubted; but the deeper problem of why the particular trade of prostitute is chosen and why many in dire poverty do not take the same course is left unanswered.

Sociological studies have suggested that some causes may be found in the existence of urban areas with high rates of juvenile and adult crime, prostitution, gambling, drug addiction, and alcoholism. In such areas subcultures have been identified in which the members are alienated from the standards and aspirations of the larger society; they live with and tend to accept the mores of the underworld (see CRIME; CRIMINOLOGY; JUVENILE DELINQUENCY). In such a milieu a girl might aspire to be a gangster's mistress, or to wear a fur coat earned by prostitution. Drug addiction has been cited as a growing factor in the recruitment of prostitutes and in keeping them in the trade. The majority of drug addicts are young adults from the underprivileged areas of large cities. They are mainly unemployed and uninterested in employment other than to maintain their drug supply, largely by crimes against property and by prostitution.

What becomes of the onetime prostitute is a matter that has never been investigated in any detail; but it is generally agreed that the majority of prostitutes do disappear. Many become charwomen or enter other low-paid employment. There is evidence to show that some marry and settle down to a conventional married life; others retire as respectable spinsters. It would be reasonable to conclude that with maturation a greater emotional stability is achieved; on the other hand, the increase in years would result in a loss of attractive power.

No approach can be made to the subject of the prostitution of women unless the counterpart, the men who constitute the demand, is considered. On the whole it is fair to say that one does not cause the other: the inclination must first be present in either party. To speak broadly, there are at least six chief types of men who frequent prostitutes, namely: young men and students in the experimental stage of development; men sexually isolated, whether for a short or for a long time, such as soldiers and commercial travelers; unmarried men; men seeking prostitutes to cater to per-

versions (see SEXUAL DEVIATIONS); married men seeking extra-marital sex; and men who have defective love-objects, such as the pimp and the gigolo.

The gigolo is generally of good education, well-dressed, and pleasing to women. He attaches himself to older women of wealth, who provide for him, and at the same time carries on relations with others. The pimp, less-educated counterpart of the gigolo, lives on a prostitute's earnings, arranges her work, and treats her, generally, with brutality.

It is sometimes said that female homosexuality is linked with prostitution as a cause or precipitating factor. It is difficult to say how much reliance can be placed upon this asseveration. Research workers have records of prostitutes with strong and acknowledged homosexual inclinations; and the opinion that this inclination is developed in a marked degree during terms of imprisonment or confinement in reformatories is notably supported by information gathered from prostitutes in Denmark.

Exclusively male prostitution, that is, the prostitution of males to males, though it clearly falls within the definition of prostitution, is invariably treated as a distinct phenomenon, being altogether inseparable from the general problem of homosexuality.

In conclusion it should be mentioned that Cesare Lombroso and Guglielmo Ferrero were of the opinion that the natural form of regression in women was prostitution, not crime. This point of view might at first seem to be at variance with the main arguments set forth in this article. It does, however, accord with the hypothesis that in many women sexual activity is a substitute for antisocial behaviour—a view supported to some extent by criminal statistics and by many persons who have been associated with female criminals.

PROTACTINIUM, a chemical element, has the symbol Pa, atomic number 91, and chemical atomic weight 231.05. It is the second member of the rare-earthlike transition series, the actinide series, which includes the elements of atomic numbers 89 to 103 inclusive, and in which an inner electronic shell (the 5f shell) is being filled, but it also resembles tantalum in its chemical properties. The first isotope (mass number 234) was discovered in 1913 by K. Fajans and O. H. Göring, who named it "UX₂" or "brevium." The long-lived isotope, Pa²³¹, was discovered by O. Hahn and L. Meitner in 1917, and independently by F. Soddy and J. A. Cranston at about the same time. The name for this isotope, protactinium (progenitor of Ac²²⁷), has now been generally adopted for element 91. Over a dozen radioactive isotopes, natural and artificial, are known, of which Pa²³³ is of especial interest as the progenitor of fissionable U²³³ produced by the absorption of neutrons in thorium.

The isotope Pa²³¹ (half-life 34,300 years) is a member of the natural (4n + 3) radioactive family and exists in uranium ores to the extent of 0.34 parts per 1,000,000 parts of uranium. From this source the first pure protactinium was isolated by A. V. Grosse and others in 1934. Protactinium can also be synthesized in quantity by irradiation of ionium (Th²³⁰) with neutrons from nuclear reactors.

Metallic protactinium is quite electropositive. The element displays the tetrapositive and pentapositive oxidation states with an estimated potential of +0.1 volts for the Pa(IV) → Pa(V)

couple. The former state behaves like the other tetrapositive actinide elements in aqueous solution and in the solid compounds. The pentapositive state undergoes hydrolysis so readily that it is extremely difficult to keep in acidic solution, and complexing agents such as fluoride ion are often used for this purpose. Included among the identified solid compounds are Pa₂O₅, PaO₂ (and intermediate oxides), PaH₃, PaF₄, PaCl₄, PaOS, and probably PaBr₄, PaI₄, PaN₂, PaF₆, PaCl₅, PaBr₅, and PaI₅.

(G. T. SG.)

PROTAGORAS (c. 490–after 421 B.C.), of Abdera in Thrace, was the first and the most famous of the Greek Sophists. He is a principal character in Plato's *Protagoras*. His work entitled *Truth* began with the statement "Man is the measure of all things," which was probably intended to express the relativity to the individual of all perceptions and, as some hold, of all judgments as well. In *Concerning the Gods* he professed agnosticism as to whether the gods exist or not. Protagoras was perhaps the first to study grammar systematically. He professed to teach the art of politics and, as a friend of Pericles, he had considerable success in Athens, exercising a great influence over contemporary thought on moral and political questions. See also SOPHISTS.

For fragments and testimonia see H. Diels and W. Kranz, *Fragmente der Vorsokratiker*, vol. ii, 7th ed. (1954). See also M. Untersteiner, *The Sophists*, Eng. trans. (1954).

(G. B. KD.)

PROTEACEAE, the protea family of plants, about 60 genera and 1,400 species of trees and shrubs confined mainly to the Southern Hemisphere, mostly in Australia (750 species) and South Africa and Madagascar (350 species), but also occurring in Malaysia, southeastern Asia, certain South Pacific islands, and in America from southern Mexico to Tierra del Fuego. In warm regions several species are cultivated as ornamentals, including silver tree (*Leucadendron argenteum*), Australian honeysuckles (*Banksia*), and hakeas (*Hakea*). Silk oak (*Grevillea robusta*), native to Australia, is widely known as a roadside and shade tree in the southern U.S. Queensland nut or macadamia (*Macadamia ternifolia*) is grown for its edible seeds. The family contains several timber trees. The simple or divided leaves are typically spirally arranged. The flowers, uni- or bisexual, have a four-parted perianth and are disposed in often dense and showy clusters. Stamens are four, and the ovary is one-celled. The fruit, containing one to several seeds, may be fleshy or dry.

(J. W. TR.)

PROTECTORATE, a term used in international law to describe the relationship between two states, one of which exercises control over the other. The use of the term to designate such a relationship is comparatively modern; it is significant that the word does not occur in Sir George Cornewall Lewis's *Essay on the Government of Dependencies* (1841). Nevertheless the relationship is an ancient one. There have always been states which dominated their neighbours, but which did not think it politic to annex them. Edouard Engelhardt and other writers on the subject have collected a large number of instances in antiquity in which a true protectorate existed, even though such terminology was not used. Thus the hegemony of Athens, as it existed about 467 B.C., was a form of protectorate; although the subject states were called allies, they were, in all important legal matters, obliged to resort to Athens.

In dealing with dependent nations Rome used terms which veiled subjection. Thus the relationship of subject or dependent cities to the dominant power was described as that of *clientes* to *patronus*. Such cities might also be described as *civitates foederatae* (allied communities) or *civitates liberae* (free communities). Another expression of the same fact was that certain communities had come under the power (*in deditionem*) or under the trust (*in fidem*) of the Roman people. The kingdoms of Numidia, Macedonia, Syria and Pergamum were examples of protected states, their rulers being termed *inservientes* (subjects). The Romans drew a distinction between *foedera aequa* and *iniqua* (equal and unequal treaties). The latter created a form of protectorate, the protected state remaining free.

In medieval times this relation existed, and the term protection was in use, but the relationship of subordination of one state to another was invariably expressed in terms of feudal law. One state was deemed the vassal of another, and the ruler of one did homage to the other. In his work *De la République* (1576) Jean Bodin treats of "those who are under protection" or as the Latin text has it, *de patrocinio et clientela*. In Bodin's view such states retain their sovereignty (i, c, 8). Discussing the question, whether a prince who becomes a *cliens* of another loses his *majestas*, he concludes that, unlike the true vassal, the *cliens* is not deprived of sovereignty. Elsewhere he remarks, "the word protection is special and implies no subjection on the part of the party under protection." He distinguishes the relation of *seigneur* and *vassal* from that of *protecteur* and *adherent*. At times letters of protection were granted by a prince to a weak state, as, for example, by Louis XIII in 1641 to the prince of Monaco.

Reverting to the distinction in Roman law, Hugo Grotius and Samuel von Pufendorf, with many others, treat protection as an instance of unequal treaties; that is, "where either the promises are unequal, or when either of the parties is obliged to harder conditions."

In the 16th century, the rise of European national states led to increasing use of the system of protectorates as a prelude to annexation, particularly by France. This use was also developed during the 19th century as a means of colonial expansion. After the Napoleonic Wars, however, establishment of protectorates by the great powers became a means of maintaining the balance of power. Thus, by the treaty of Paris (1815) the Ionian Islands became a protectorate of Great Britain in order to prevent Austria from gaining complete control of the Adriatic. The gradual elimination of the smaller European states by the unification of Italy and Germany, and the strengthening and neutralization of those that remained (e.g., Switzerland and Belgium), brought to an end this development in the use of the protectorate. A curious situation arose, however, with the disintegration of the Ottoman empire. Provinces which owed allegiance to Turkey began to revolt against Turkish rule and, as a stage in their struggle for independence, were sometimes placed under the protection of a foreign power. Thus, Moldavia and Walachia, which became protectorates of Russia in 1829, were placed under international protection in 1856 and in 1878 united to form the independent state of Rumania (q.v.).

Definitions.—"The one common element in protectorates is the prohibition of all foreign relations except those permitted by the protecting state. What the idea of protectorate excludes, and the ideas of annexation, on the other hand, would include, is that absolute ownership which was signified by the word *dominium* in Roman law, and which, though not quite satisfactorily, is sometimes described as territorial sovereignty. The protected country remains, in regard to the protecting state, a foreign country; and this being so, the inhabitants of the protectorate, whether native-born or immigrant settlers, do not by virtue of the relationship between the protecting and the protected state become subjects of the protecting state." (Sir William Rann Kennedy, *Rex v. Crewe*, 1910, 2 K.B., 576.)

The term protectorate is used loosely to designate a variety of degrees of control of one state by another, from that situation in which it means no more than that the protecting state guarantees and protects the safety of the other, to a situation which is a masked form of annexation, in the manner of the German protectorates established in Czechoslovakia in March 1939. Strictly, it is distinguished from suzerainty, but nevertheless both relationships display the same characteristics of the observance of such ancient forms and traditions in the protected state as are consistent with necessary change, and the reservation of nominal freedom while securing real power to the protecting state. Protectorate is probably best regarded as a form of international guardianship and the modern emphasis is upon the responsibility and duty of the protecting state to the international community as well as to the protected state.

There are two principal classes of protectorates, those exercised over more highly civilized countries having a stable form

of government and a historical tradition of their own, and those exercised over underdeveloped peoples, the latter being sometimes called colonial or pseudo-protectorates and being especially common in Africa. Examples of the former exist in Europe in Andorra and San Marino. Strictly, there can be no protectorate over a domain which is uninhabited or ruled by no organized state, but the distinction has not always been maintained.

In its narrowest and strict meaning, the relationship established in a protectorate must be distinguished from the relationship existing between the United States and the states of Central and South America (see PAN-AMERICAN CONFERENCES and MONROE DOCTRINE), from the former relationship between Great Britain and the Indian states (see INDIA-PAKISTAN, SUBCONTINENT OF) and from so-called spheres of influence (q.v.).

Protectorates and International Law.—"The extent of the powers of a protecting state in the territory of a protected state depend, first upon the treaties between the protecting state and the protected state establishing the protectorate, and secondly upon the conditions under which the protectorate has been recognized by third powers as against whom there is an intention to rely on the provisions of these treaties. In spite of common features possessed by protectorates under international law, they have unlimited legal characteristics resulting from the special conditions under which they were created, and the stage of their development." (*Advisory Opinion, The Nationality Decrees in Tunis and Morocco*, "Series B," no. 4, p. 27, 1923.)

The majority of protectorates have been established by treaty by the terms of which the weaker state surrenders the management of all its more important international relations, although some have been imposed by force, e.g., the unilateral declaration by Great Britain concerning Egypt in 1914 (see EGYPT). The treaty defines the position of the protected state in the international community, with special reference to its treaty-making powers and its right to diplomatic and consular representation.

There is a conflict of opinion whether or not the protected state loses its sovereignty. Many writers have supported the view that there is no such loss, and have gone so far as to state that the arrangement is *res inter alios acta* ("a thing done between others"), and concerns only the parties to it. This is not the modern view, however, and it is now generally accepted that the relationship of protectorate must be recognized by third powers. The right of the protecting state to interfere in all matters of external affairs constitutes a definite loss of sovereignty, and since in orthodox theory sovereignty is one and indivisible, such a situation must imply a loss of sovereignty on the part of the weaker state. Neither position is without its anomalies; for example, it is clear that the sovereign of the weaker state yet has jurisdictional immunity in at least the territory of the protecting state (see *Duff Development Co. v. Kelantan [Government]* and A. G., 1924 A.C. 797).

On the other hand, it was equally clear that on the assumption of the status of protectorate, the weaker state ceased to qualify for membership in the United Nations.

The relationship does not affect the nationality of the members of the weaker state, although there are frequently facilities for the peoples of the protectorate to become nationals of the protector, and they owe a certain ill-defined allegiance to the protecting state. Thus the British Nationality act, 1948, made provision for the naturalization of British protected persons the requirements to be fulfilled being less onerous than those imposed upon aliens. Nor, generally speaking, does the territory of the protectorate become part of that of the protecting state, although the applicability of legislation of the dominant state can only be judged from the construction of its terms.

The older view of the position of a protectorate according to international law is contained in the decision of Stephen Lushington in "The Case of the Ionian Ships" (2 Spink 212, 164 E.R. 394 [1855]). The Ionian Islands were at that time subject to the protectorate created by the treaty of Paris, 1815, and it was held that notwithstanding the declaration of war by Great Britain against Russia, the Ionian Islands remained neutral. It was not disputed that as the head of the protecting state the British sov-

ereign had the right to declare war or make peace on behalf of the islands "Such a right is inseparable from protection." But the intention to involve the protected state in the wars of the protecting power must be clearly expressed, and the state of war does not arise *ex necessitate* on the protecting power's going to war, for there may very well be advantages to one or other of the parties to the protectorate if the protected state is not so involved. It is said that the protected state is only implicated in the wars to which the protecting state is a party where the latter has acquired a right of military occupation of the territory of the former.

See also MANDATE; SUZERAINITY; TRUSTEESHIP SYSTEM. For current data see "Protected States, Condominiums, and Trust Territories" in *Britannica Book of the Year*, American edition. (E. H. LD.)

PROTEINS are highly complex substances that are universally present in living organisms. They are of great nutritional importance, have numerous industrial uses and are directly involved in the chemical processes necessary for the maintenance of life. After water has been removed from the soft tissue of an animal, whether it be the human body or a one-celled animal, the major portion of the solid residue is found to be a mixture of proteins. Proteins make up about 80% of the dry weight of muscle, 70% of the dry weight of skin and 90% of the dry weight of blood. The interior substance of plant cells is also composed largely of proteins.

Biological Function.—Some proteins, such as those of hair, wool, silk and bone, serve an obvious structural function for the organism that has made them. Other proteins, such as those of milk, eggs and seeds, are accumulated as storage depots of food for the young, growing organism. The proteins in the above two categories are extracellular. Another group of proteins present within the living cells participates very directly in the chemical processes essential for the existence of the cell. These proteins serve as specific catalysts, or enzymes (*q.v.*), bringing about and directing the chemical processes of metabolism. It is impossible to describe life processes at a molecular level without taking into consideration the functional role of the enzymes. There appears to be at least one kind of enzyme for each type of chemical reaction that occurs in a cell. Since there are a large number of such reactions, it follows that there are a large number of different enzymes.

The central role of proteins in biochemical processes was recognized by chemists in the early 19th century when they coined the name for these substances from the Greek word, *proteios*, meaning "holding first place."

Proteins in Nutrition.—Green plants and many microorganisms do not require protein food. For man and all animals, however, protein is an essential constituent of the diet. Without it death is inevitable. Strictly speaking, it is not protein itself that is required, but the building blocks of protein, the amino acids (see below). A protein molecule is very large compared to molecules of sugar or salt, and consists of a large number of amino acids joined together to form long chains, much as beads are arranged on a string. In the digestive tract of the animal, enzymes act to degrade the protein of the food by breaking these long chains into shorter chains and free amino acids. The amino acids are absorbed across the walls of the intestinal tract and transported by the blood to the tissues. The cells then assemble their own proteins from these amino acid building blocks. Each species of animal or plant has a unique set of proteins different from those of other species. This difference is the reason that an animal cannot make direct use of the protein of a plant or of another species of animal, without first breaking that protein down to amino acids.

There are about 20 different amino acids that occur naturally in proteins (see Table). About half of these can be synthesized from other materials in the cells of the animal body. Eight of these amino acids cannot be synthesized by the human body, however, and must therefore be furnished in the diet (see Table). Normally, these essential amino acids are furnished in the form of protein food. The nutritional requirements of an animal for protein can actually be satisfied by feeding a mixture of essential

amino acids, but since adequate amounts of such a mixture would be very expensive and not very palatable, there is little likelihood that man will substitute amino acids for good protein food such as meat, milk and eggs. It is striking that the proteins produced in nature for the nourishment of the young (for example, the milk proteins of mammals, the egg proteins of birds and the proteins laid down in seeds by plants) all provide adequate amounts of the essential amino acids. A diet that includes an inadequate supply of one or two essential amino acids, but is otherwise adequate, can be improved by adding the particular amino acids that are in short supply. It is also possible to feed an individual, who may for some reason be unable to ingest food, by intravenous injection of amino acids. The intact protein of ordinary foods cannot be used in this way.

Growth experiments have shown that all of the essential amino acids must be ingested simultaneously if they are to be utilized effectively. If the essential amino acids in the protein of the diet are balanced, then the minimum requirement of a man of average size is about 44 g. of protein a day. In 1943 the United Nations Conference on Food and Agriculture adopted certain dietary allowances that were regarded as the desirable goal for all peoples of the world. These recommendations included the following average values for protein in grams per day: man, 70; woman, 60; woman in the latter half of pregnancy, 85; woman in lactation, 100; girls 16 to 20 years, 75; and boys 16 to 20 years, 100. These goals are based on the assumption that an adequate number of calories and an adequate supply of vitamins are included in the diet. Authorities differ on these values, some setting the requirements appreciably higher.

Metabolism of Protein.—At first thought there may seem to be no reason why an adult should require protein in the diet, since an increase in the mass of body proteins occurs only during growth. Protein is continuously lost from the body, however. The proteins of dying cells, denatured protein and degradation products are broken down into amino acids by enzymes of the tissues. Some of these amino acids find their way back into new proteins. The remainder are degraded further, along with the amino acids that have been taken in the food and which are left over from protein synthesis. All of the amino acids contain nitrogen in the form of an amino group. This nitrogen is converted into urea by the liver, and the urea is excreted as a waste product in the urine. The normal adult excretes between 7 and 15 g. of nitrogen per day. The carbon compounds that remain after the removal of nitrogen are oxidized by the tissues into carbon dioxide and water. In this process the proteins may supply energy to the body. Normally, less than 20% of the energy requirements are supplied by the burning of protein. In the latter stages of starvation, however, large amounts of the tissue proteins are burned away.

The continuous breakdown and synthesis of new protein results in the renewal of all of the proteins in the body. Some tissue proteins are more susceptible to change than others. For example, the proteins of the liver, the blood plasma (but not the red cells) and the lining of the intestine are broken down very rapidly, whereas the proteins of muscle, skin, brain and skeleton are broken down slowly. The average life of the hemoglobin in the red cells is about 120 days, but the serum albumin of the blood is renewed in a few weeks.

Proteins and Immunity.—When a protein of a different species is injected into the blood stream of man or an animal, an immunity to that protein may develop. Antibodies to the foreign protein appear in the blood stream. The antibody is itself a protein that has the ability to combine with the foreign protein eliciting its formation. If the foreign protein has toxic properties, these are thereby neutralized. By this mechanism the animal protects its body from invasion by bacteria. The bacterial proteins induce antibody formation that renders the bacteria harmless and incapable of invading the animal.

Industrial Use of Proteins.—Since animal tissues contain a much higher proportion of protein than plant tissues, most of the proteins of industrial importance are obtained from animal sources. Apart from the food proteins, the proteins which are utilized in the largest quantity are keratin found in wool and

fibroin in silk of the textile industry (see WOOL; SILK: *Physical and Chemical Properties of Silk*), and collagen in the processed hides of the leather industry (see LEATHER). Glues and sizes are prepared from the casein (*q.v.*) of milk, from the proteins of blood and from the crude gelatin of boiled bones. (See ADHESIVES.) Bone protein, called ossein, is similar to collagen. The gelatin (*q.v.*) used as food is obtained from scraps of hide, connective tissue and tendons. Waste proteins, including blood, horn, hooves, bones, etc., are used for plant fertilizer as a source of organic nitrogen.

The plant protein, zein, is a by-product of the starch industry. After starch has been extracted from corn (maize), the protein is separated from the residues by extraction with isopropyl alcohol, in which it is soluble. Zein has industrial uses similar to those of casein. Both proteins have been used to a limited extent in the manufacture of yarns. Seed proteins such as those from the soybean and the peanut have been converted into plastics. Wheat yields a protein, gluten, which is rich in glutamic acid and serves as a source for the condiment monosodium glutamate. Another protein used in cookery is papain from the papaya plant, an enzyme which is applied to meat before cooking in order to make it more tender. Soybean protein is used increasingly in the preparation of synthetic foods. The protein is spun into delicate fibres, which are combined and artificially flavoured and textured to resemble meats and other natural products.

Properties of Proteins.—Proteins vary greatly in their properties. Some, such as the bright red hemoglobin of blood, contain pigments built into the molecule. Other proteins are colourless. Some proteins, such as hair, wool and silk, form long thin fibres completely insoluble in ordinary solvents. Others, for example the albumin of egg white, are very soluble in water but solidify on heating. Muscle cells contain fibres of protein that have the property of contracting and relaxing when the cell is stimulated. All proteins have the common property of being built from the same subunits, the amino acids, according to the same general plan. The amino acids are joined together by primary bonds, called peptide bonds, to form long chains. About 20 dif-

ferent kinds of amino acids are present in one protein molecule, but there may be a hundred or more amino acid subunits in the molecule, some of the amino acids recurring many times along the length of the chain. The sequence of amino acids along the chain is characteristic for each protein. It is clear that the number of possible arrangements of amino acids in the chain is very large, thus explaining why there are such an enormous number of different kinds of proteins.

Proteins, as they are found in nature, are characterized not only by the sequence of amino acids in their chains but also by the three-dimensional configuration of the chains themselves. Certain atomic groupings along the chains are able to form bonds with one another and to stick together. As a result, the chains are held in definite coiled or folded configurations. The properties and biological function of each protein depend upon the maintenance of a specific configuration. Larger aggregates are also formed, composed of several, or even a very large number, of molecules, held together more or less firmly. Since the structure of the native protein molecule is organized in a specific way, it follows from the geometry of these molecules that the structure of the aggregate is also organized into a pattern. Thus the structure of proteins is organized at three levels: (1) the sequence of the amino acids in the chains; (2) the folding of the chains into functional units; and (3) the combination of these units into larger patterns. It is this ability to form organized structures of great complexity and variety, inherent in the chemical nature of proteins, that is the basis for their function in living matter.

Differences in solubility are sometimes used for classifying proteins, but as more is learned, this basis of classification loses its usefulness. Frequently the more soluble fraction of a mixture of proteins is called the albumin fraction, and the less soluble fraction is called the globulin fraction. Albumins are soluble in pure water, whereas true globulins are insoluble in water but are soluble in dilute salt solutions. Proteins insoluble in water or in salt solutions may dissolve in dilute acid or dilute alkali. High concentrations of a salt such as ammonium sulfate will precipitate

both albumins and globulins. The chemist makes use of these differences in solubility for the isolation and purification of individual proteins.

Molecular Size.—Many properties of proteins result from their large size. They are very large compared with a molecule of water, which has a molecular weight of about 18 times the weight of a hydrogen atom, or compared with a molecule of cane sugar, which has a molecular weight of about 342. Though some proteins may have a molecular weight as small as 6,000, others have molecular weights greater than 100,000. Some aggregates of protein molecules, uniform in size and composition, are known to have particle weights greater than 1,000,000; e.g., the virus proteins. Since protein molecules are very heavy, they can be caused to fall out of solution in a large centrifugal field. High-speed centrifuges (ultracentrifuges) are used to determine the molecular weight of proteins by measuring how fast they will move to the bottom of a rotating vessel.

Compared with smaller molecules, proteins in solution diffuse very slowly from one place to another in the liquid. Those proteins with the shape of long, thin rods give viscous solutions. The large size of proteins prevents them from diffusing through natural membranes such as the walls of the blood vessels or through synthetic membranes such as cellophane, whereas molecules as small as sugar diffuse freely. As a consequence, proteins are able to produce a permanent osmotic pressure across a membrane. That is, pressure is required to prevent water placed on one side of the membrane from penetrating into the protein solution placed on the other side of the membrane.

Denaturation.—Unlike most simple organic molecules, the physical and chemical properties of a protein are markedly altered when the substance is boiled in water. Similar changes are produced by the following reagents: dilute acid, dilute alkali, alcohol, detergents or concentrated solutions of urea. The process by which these reagents alter the protein is called denaturation. In general, denaturation results in lowered solubility of the protein in neutral solution. In some cases, a gel or coagulum is formed, as when egg white is heated. More significantly, denaturation usually results in the loss of the biological function of the protein. For example, enzymes lose their catalytic powers and hemoglobin loses its capacity to carry oxygen. The changes that accompany denaturation have been shown to result from the destruction of the specific pattern in which the amino acid chains are folded in the native protein. All of the agents able to cause denaturation are able to break the secondary bonds that hold the chains in place. Once these weak bonds are broken, the molecule falls into a disorganized tangle, devoid of biological function.

Conjugated Proteins.—Some proteins contain other chemical groups in addition to amino acids. Such proteins are called conjugated proteins. If the nonprotein portion of the molecule is known to have a biological function, it is referred to as the prosthetic group. A large number of enzymes have prosthetic groups that participate in the catalytic activity. Some of these prosthetic groups are derived from vitamins (see VITAMINS; ENZYMES). If the prosthetic group is coloured, the conjugated protein which contains it will also be coloured. For example, hemoglobin, the main constituent of the red cells of blood, consists of the protein globin and a coloured substance called heme. Four heme molecules, each of which contains one iron atom, are firmly attached to each globin molecule. In the lungs, an oxygen molecule is bound to each iron atom and is carried by the blood stream to the outlying tissues. Other proteins are known that contain metal atoms bound to the protein structure. The cerulo-plasmin of blood is a bright blue protein containing copper.

Proteins and Heredity.—The most important conjugated proteins are the nucleoproteins, which consist of proteins combined with nucleic acids (*q.v.*). Nucleoproteins are found not only in the nuclei of cells, but also in extranuclear particles. Chromosomes, viruses and the heads of sperm cells all consist largely of nucleoproteins. These substances serve the mechanism by which hereditary characteristics are transmitted from cell to cell and are intimately involved in the processes of self-duplication which are basic to life.

Amino Acids.—Proteins may be broken down into their constituent amino acids by prolonged heating with acid, by heating with alkali, or by treatment with certain enzymes which cause a breaking of the bonds between the amino acids. Molecules of the natural amino acids have the common structure shown in the formula:

As indicated by the structure, the four covalent bonds of the α -carbon atom are linked to an amino group ($-\text{NH}_2$), a carboxylic acid group ($-\text{COOH}$), a hydrogen atom ($-\text{H}$), and a fourth atomic grouping which is called the side chain ($-\text{R}$). As with all organic compounds in which a carbon atom is linked to four different groups, there are two different ways in which the groups may be arranged around the central carbon atom. Only one of these arrangements is found in the amino acids isolated from proteins, and this arrangement is designated by the symbol L. Thus the subunits of proteins are described as L- α -amino acids. The amino acids obtained from proteins are distinguished by their different side chains. The table gives the names of the most important naturally occurring amino acids and their structural formulas, and indicates the importance in nutrition of each substance.

A few additional amino acids occur in proteins only rarely, and so are not listed in the table. An example is thyroxine, an iodine-containing amino acid occurring in the protein of the thyroid gland. One of the compounds listed in the table, proline, is strictly speaking an imino, rather than an amino acid. Aspartic and glutamic acids are frequently classified as acidic amino acids; histidine, lysine and arginine are classified as basic amino acids, and the remaining amino acids are described as neutral. In actual fact, since the carboxyl group is acidic, and the amino group is basic, all amino acids are both acids and bases, but the acidic and basic groups neutralize each other, to give a molecule with the dipole structure shown:

The Peptide Bond.—Two amino acids may be joined by condensation between the carboxylic acid group of one molecule and the amino group of the other molecule, with the splitting out of a molecule of water:

The bond formed between the carbonyl group ($-\text{CO}-$) and the imino group ($-\text{NH}-$) is called a peptide bond. A dipeptide is a compound formed by the union of two amino acids through one peptide bond, such as alanyl-serine shown above. A tripeptide is formed from three amino acids joined by two peptide bonds, while a tetrapeptide is formed from four amino acids, etc. When many amino acids are linked into a chain by peptide bonds, the structure is called a polypeptide. Thus proteins may be described as molecules that are composed of polypeptide chains.

When a polypeptide chain is split into the component amino acids by the action of acid, or alkali, or certain enzymes (peptidases), the condensation reaction is reversed. A molecule of water is added to each peptide bond by a process called hydrolysis, and one carboxyl group and one amino group are reformed. If hydrolysis is not complete, the products may consist of di-, tri-, and higher peptides, besides free amino acids. The fact that proteins can be hydrolyzed to amino acids and peptides by the action of certain enzymes which are known to attack the peptide bonds of synthetic peptides provides convincing proof that the peptide bond is the principal means by which amino acids are linked in proteins. A number of simple peptides are found in nature. Among them are the pituitary hormone, oxytocin, and the tripep-

tide glutathione (*q.v.*). These peptides, and many others resembling them, have been synthesized in the chemical laboratory.

Structure of Protein.—If the structure of a protein is to be completely determined, one of the problems that must be solved is the sequence of the amino acids in the peptide chain. Methods whereby sequence can be determined are known, but the techniques are difficult and laborious. An event that marked a milestone in the advance of knowledge of proteins was the determination by Frederick Sanger (*q.v.*) in the early 1950s of the sequence of amino acids in the polypeptide chains of insulin. This

ATOMIC MODELS OF POLYPEPTIDE CHAIN (α -HELIX): (LEFT) THE CORE; (RIGHT) CORE WITH VARIOUS SIDE CHAINS ATTACHED

hormone, which counteracts diabetes, is composed of two different polypeptide chains, one 30 amino acids long and the other 21 amino acids long. Subsequent work by others resulted in the determination by the 1960s of the complete amino acid sequences of the enzyme ribonuclease and the protein subunit of the tobacco mosaic virus.

The polypeptide chains of native proteins are not free to take random configurations. They are fixed by cross-linkages between points on the same chain and between points on different chains. One type of cross-linkage is formed between the sulfur atoms of two molecules of the amino acid cysteine, giving a disulfide ($-S-S-$) bond. Another type of cross-linkage may be formed by phosphorus in the form of phosphoric acid, which may serve to link pairs of side chains.

Another type of bond prevalent in proteins is the so-called hydrogen bond formed between oxygen and nitrogen atoms. A hydrogen atom is found between the two atoms that form such a bond; *e.g.*, $O-H\cdots O$ and $N-H\cdots O$. Although hydrogen bonds are weak compared with primary bonds, the presence of a large number of hydrogen bonds in proteins results in an accumulative effect that contributes significantly to the stability of particular structures. Investigations of proteins by means of X-rays have indicated that hydrogen bonds hold portions of the polypeptide chain in a helical (spiral) configuration. A model of the helical

structure of a polypeptide chain is shown in the accompanying photograph. On the left, the side chains have been removed to show the hydrogen bonds between the carbonyl groups and the imino groups of the peptide linkages. On the right, the side chains are in place. The model demonstrates how the side chains of the different amino acids project out from a roughly cylindrical core within which the hydrogen bonds are buried. Many properties of proteins can be explained by this model.

Electrical Charge.—Although the amino acids have a dipole structure, the peptide bond is relatively uncharged. However, a protein generally contains amino acids with acidic side chains and also amino acids with basic side chains. These groups may carry electrical charges. In acidic solutions most proteins carry a positive electrical charge, while in alkaline solutions they carry a negative charge. An electrical process, called electrophoresis, is used by the chemist to analyze and separate mixtures of proteins according to the electrical charges of the molecules. (B. V.)

Natural Synthesis of Proteins.—The problem of how the living cell synthesizes protein had been all but completely elucidated by the mid-1960s. Many laboratories had clearly achieved net synthesis of specific proteins in cell-free extracts containing enzymes, nucleic acids and subcellular particles, and the detailed analysis of this interesting and important process was proceeding rapidly.

Amino acids made reactive by combination with adenosine triphosphate (*see* METABOLISM: *Bioenergetics*) become attached to molecules of a low-molecular-weight ribonucleic acid known as transfer RNA. Each amino acid, bound to its transfer RNA, then migrates to one of the subcellular particles, known as ribosomes, where it reacts to form a peptide bond with a lengthening protein chain in a specific sequence determined by a second type of ribonucleic acid, called messenger RNA. This substance originates in the nucleus of the cell where its sequence in turn is determined by that of the genetic material (*see* GENE: *Gene Composition and Replication*). Each messenger RNA molecule bears in its sequence specifications for the sequence of amino acids in a protein to be synthesized. In this way amino acids from the transfer RNA are linked together by peptide bonds in specific sequence ultimately determined by the genetic material of the cell. The result is the synthesis of a unique polypeptide structure characteristic of the cell that made it: a protein.

Artificial Synthesis of Proteins.—Although random peptide polymers of amino acids had been created by chemical means no artificial compound with properties identical to those of a naturally occurring protein had been made in the laboratory until 1964. In that year P. G. Katsoyannis and his collaborators at the University of Pittsburgh reported the synthesis, by purely chemical methods, of the two main chains of the insulin molecule. This was the next-to-last step to complete synthesis, which was achieved in 1966 by a group in China headed by Y. C. Du. (J. W.)

PROTESILAUS, Greek mythological hero, son of Iphiclus and Diomedea (or Astyoche), leader in the Trojan War of the force from Phylace and other Thessalian cities west of the Paeonian Gulf. Though aware that an oracle had foretold death for the first of the invading Greeks to land at Troy, he was the first ashore and the first to fall. His newly married wife Laodamia was so grief-stricken that the gods granted her request that Proteus be allowed to return from the dead for three hours. At the expiration of this time she accompanied him to the underworld, either by immediately taking her own life or by immolating herself in the flames in which her father burned the waxen image of Proteus she had been cherishing. The theme is a favourite with Latin erotic poets, whose source is probably Alexandrine. No extant Greek author gives the full story, though Euripides may well have used it as the plot of his lost *Protesilaus*. (D. E. W. W.)

PROTESTANT, a term applied to those Western Christian communions in separation from the Roman Catholic Church which owe their existence to the Reformation or to later events influenced by the Reformation (*q.v.*). The adherents of those communions are commonly described as Protestants and their teaching as Protestant.

The historical origin of the word is in the second imperial Diet of Speyer (1529), which reversed by a majority vote the decision of the first Diet of Speyer (1526) to allow each prince of the empire to determine the religion of his territory. The minority, consisting of 6 princes and 14 cities, issued a formal *Protestation*, the primary purpose of which was to protest that "in matters which concern God's honour and salvation and the eternal life of our souls, everyone must stand and give account before God for himself." A secondary purpose was to protest against the ban on the expansion of evangelical religion.

The supporters of the Reformation doctrines gradually came to be called Protestants both by their opponents and by themselves, since it was a convenient name to cover the many varieties of Reformed Christianity. It spread from the continent of Europe to England, where, since 1689, the coronation service has contained an oath to defend the "Protestant Reformed Religion by law established." The non-Anglican Reformed churches in Great Britain have accepted the name as a true description of themselves since the 17th century, and this is the case also in America and the other English-speaking countries. But no communion incorporated the word into its title until this was done by the Protestant Episcopal Church of America. The 19th-century Oxford Movement persuaded an increasingly large number of clergy and laity of the Church of England to repudiate the word "Protestant" as a description of their church. The term is officially used on both sides of the Atlantic by a number of societies which propagate the view that the principles of the Reformation are being neglected.

The basic doctrines of Protestantism at the Reformation, in addition to those of the creeds, were: the supremacy of Holy Scripture in matters of faith and order; justification (*q.v.*) by grace alone through faith alone; the priesthood of all believers. There has been variation in sacramental doctrine among Protestants, but the limitation of the number to the two "sacraments of the Gospel," baptism and Holy Communion, has been almost universal. In the 18th century the Enlightenment produced liberal Protestantism, which cast doubt on some doctrines in the creeds and stressed reason, religious experience, and the principle of private judgment in a way that would have been repugnant to the original Reformers. But this form of Protestantism was a spent force by the end of World War I, and by the efforts of thinkers such as Søren Kierkegaard and Karl Barth (*qq.v.*) Protestant theology and devotion have regained their objectivity with, at the same time, a deeper appreciation of the values of pre-Reformation Christianity. Though the doctrine of the verbal inerrancy of Scripture is maintained by several Protestant groups, the supremacy of the biblical revelation usually has been reasserted without it.

PROTESTANT EPISCOPAL CHURCH. The Protestant Episcopal Church in the U.S. is the denomination which was formed as successor to the Church of England in the American colonies and extended into all of the United States and its territories, with missionary districts in more than a dozen other countries. Associated with other autonomous churches in the Anglican Communion, it has a membership of about 3,500,000 baptized persons (including infants and young children) of whom about 2,500,000 are communicants (registered recipients of Holy Communion, generally 12 years of age or older). Distinctly Protestant in many features of life and doctrine, including its teachings about Scripture, justification, and the priesthood of believers, the church has remained catholic in appreciating the whole Christian heritage and in comprehending a diversity of faith and practice into a unified but not uniform Christian body. The members are organized into about 7,500 congregations, served by as many clergymen, grouped in approximately 100 jurisdictions called dioceses. The dioceses have federated to form the denomination, whose central administrative body is the Executive

Council, with headquarters in New York City.

HISTORY

Origins.—In points of doctrine, worship, and ministerial order the church descended from and has remained affiliated with, and therefore traces its origin to that of, the Church of England, which achieved its distinction from Roman Catholicism under Tudor monarchs in the mid-16th century. (*See ENGLAND, CHURCH OF.*) While doctrine, discipline, and worship were then fully reformed and have remained so, Reformation leaders were careful not to break the line of England's bishops from the traditional episcopal succession of the medieval and patristic periods (*see EPISCOPACY*). Hence the church has claimed connection with the whole of Christian tradition and has cherished the recollection of pre-Reformation episodes in which English rulers and ecclesiastics asserted independence from the papacy.

More particular origins lie in the settlement and activity of the Church of England in the American colonies. Worship services had been conducted in the Colonies by clergy accompanying groups engaged in exploration, but continuous history in the New World began with the Jamestown settlement in 1607. Although it was the established church in the Virginia colony, New World conditions soon produced such innovations as local, lay government through vestries. As colonial policy changed after the accession of William and Mary, church establishment obtained also in Maryland, in five southern counties of New York, in Georgia, and in the Carolinas. The same policy secured for the church the right to exist as Nonconformist under New England's Puritan establishments, and by 1700 it had gained a foothold also in the religiously tolerant middle colonies.

Where local or colonial maintenance was inadequate, growth was fostered by the Society for the Propagation of the Gospel in Foreign Parts. The society was founded through efforts of Thomas Bray, who was superintendent of clergy in Maryland, but whose major work was enlisting public and private support for the church's religious and educational work in the Colonies. All that work was under the absentee jurisdiction of the bishops of London, some of whom appointed commissaries such as Bray in Maryland to act locally in their stead. Existing in every colony by the time of the Revolution, the church was insignificant in only a few.

BY COURTESY OF THE CHURCH HISTORICAL SOCIETY

THOMAS BRAY (1658-1730), FOUNDER OF THE SOCIETY FOR PROMOTING CHRISTIAN KNOWLEDGE (1698) AND THE SOCIETY FOR THE PROPAGATION OF THE GOSPEL (1701)

Both the quest by many colonists for freedom from royal ecclesiastical control and the difficulties of adapting a royal, episcopal, established church to colonial conditions kept the Church of England from achieving in America the broad membership it enjoyed at home. Having no bishop in the Colonies meant a journey to England for any colonist entering the church's ministry, robbed congregations and clergy of episcopal visitations and supervision, left the rite of confirmation in total neglect, and deprived colonial churchmen of effective channels of appeal to the church at home. Several efforts to obtain bishops for the Colonies failed in the face of steady Puritan protest and of intermittent royal apathy. At the outbreak of the Revolution there were fewer than 300 Church of England congregations in the 13 Colonies. Of the 250 clergymen, half of whom were in Maryland and Virginia, the large majority were faithful to the oath of allegiance to the crown made at the time of ordination. In the South, however, the Revolution enlisted many churchmen into its leadership, and in Virginia two-thirds of the clergy supported independence. As an agency of the crown the church naturally fell under suspicion and attack, especially where its members

were royalist, in spite of the fact that two-thirds of the signers of the Declaration of Independence were enrolled as churchmen.

Development in the United States.—Even before the end of the Revolution a prominent clergyman, William White (*q.v.*), chaplain of the Continental Congress, proposed that congregations form themselves into an American church continuing the spiritual legacy of the Church of England but severing jurisdictional connections with that church and the crown. Conventions of clergy and laity were held in various states in the early 1780s both to claim church property where establishment was annulled and to authorize entering into negotiations toward forming a distinct denomination. Interstate conventions in 1784 and 1785 began to draft a constitution and prayer book. Appeals were made to the Church of England to consecrate bishops for the new Protestant Episcopal Church; White was consecrated for Pennsylvania and Samuel Provoost (*q.v.*) for New York on Feb. 4, 1787. Earlier, Connecticut clergy, acting independently, had sought to have a bishop consecrated in England for their congregations; failing that, Samuel Seabury (*q.v.*) was consecrated in Scotland by non-juring bishops, schismatics from the Church of England, on Nov. 14, 1784. When the denomination was formally organized in the General Convention at Philadelphia in 1789, Seabury was recognized by representatives from

other states as a bishop, and New England delegates accepted the revised constitution and prayer book. The following year saw the consecration in England of James Madison for Virginia. All four bishops joined in consecrating Thomas John Claggett for Maryland in 1792, thus making the episcopal order self-sustaining and continuous with that of the mother church.

With its own government, liturgy, and ministry, the church was organized for work. But for a generation it lay dormant. At the General Convention of 1811 only one of the six bishops attended, and there were few more clergy and laymen present than in 1789. A new generation brought vigorous leadership ready and able to adapt the church to the generally American religious impulses of revivalism and denominationalism. John Henry Hobart, who became bishop of New York in 1811, emphasized the peculiar heritage and character of the church in competition with other denominations, enlarging membership, fostering westward expansion, and establishing institutions such as General Theological Seminary in New York. Alexander Viets Griswold became bishop of Massachusetts, Maine, New Hampshire, and Vermont, and increased congregations and membership fivefold through itinerant evangelistic work. In Virginia the evangelical Bishop Richard Channing Moore, by fostering revivals, extralitururgical services, and a theological seminary, reawakened that state's "mother church." High churchmen and evangelicals formed the Domestic and Foreign Missionary Society in 1820 to extend the church westward and abroad. The society, after 1835 the official missionary agency to which all church members belonged, established and staffed missionary districts in all the sparsely settled areas of the growing United States. The energetic work which Philander Chase (*q.v.*) had performed in Ohio and Illinois became the pattern for Bishops Jackson Kemper in the Northwest, Leonidas Polk and James Hervey Otey in the Southwest, and others. In 1853 a bishop was consecrated for California, in 1854 others for Oregon and Iowa, in 1859 one for Minnesota, and so on. In the United States, rapidly becoming more populous through expansion and immigration, the church burgeoned from a proportion of 1 communicant to 400 population in 1830 to 1:107 in 1900. Abroad, an educational mission to Greece began in 1829, followed by the

founding of missions in Liberia in 1835, China in 1840, Japan in 1859.

High and Low Church Divisions.—The Oxford Movement (*q.v.*) of the Church of England became influential during the 1840s, broadening the church's tradition, enriching worship and spiritual discipline, sharpening denominational claims, and exciting espousal among high churchmen and opposition among low churchmen. In 1853 a prominent group of churchmen joined William Augustus Muhlenberg, a New York rector, in pleading that the church rise above partisanship to champion union with other denominations in evangelizing the nation. Too daring for its day, the plea only moderated the churchmanship controversy which by then involved questions not only of sacerdotal authority but also of ritual, ceremonial, sacramental worship, ecclesiology, and doctrine. Interrupted by the Civil War, the controversy raged again, by 1873 with violence that split the church. While some high churchmen championed a view of the intimate kinship of Anglican and Roman Catholic churches, low churchmen were unable to accomplish an official definition of Episcopalianism's Protestant principles and practices. George David Cummins (*q.v.*), then assistant bishop of Kentucky, was attacked for officiating at the united communion service of the sixth General Conference of the Evangelical Alliance in New York, October 1873. Resigning his charge in the Episcopal Church, Cummins, joined by seven clergymen and a score of laymen, organized in December 1873 the Reformed Episcopal Church, rejecting the notion of the episcopacy as an order of ministry while holding it as an office of presidency among equal presbyters.

Later History.—During the Civil War the dioceses of the Protestant Episcopal Church in seceded states judged themselves

under necessity to establish a separate church administration, but the church was reunited by 1866. During the war new theological schools were established at Cambridge, Mass., and at Philadelphia, and soon afterward a church-controlled university at Sewanee, Tenn. These schools promoted liberal theology and biblical criticism in the church, forces which along with the social gospel and ecumenical movement have mitigated the internal controversy over churchmanship. The church has participated fully in the affairs of the Anglican Communion since the beginning of decennial Lambeth Conferences (*q.v.*) of Anglican bishops in 1867. In 1910 the General Convention inaugurated a movement toward ecumenical discussion of faith and order, issuing in the great conferences at Lausanne (1927), Oxford (1937), and Amsterdam (1948), at the last of which this movement became a part of the World Council of Churches.

After World War I the church created a permanent, representative, administrative body known as the National (later Executive) Council, which took over the functions of the Domestic and Foreign Missionary Society as trustees. Foreign missionary work, which had grown especially in Latin America and the Philippines, was consolidated. The council approached domestic missionary work more sociologically than geographically. Social and educational functions of the church were given a concern commensurate with the emphasis laid upon them by the revised prayer book of

BY COURTESY OF THE CHURCH HISTORICAL SOCIETY

1892. A renewed interest in worship which produced that revision was further stimulated by its allowance of liturgical variation and experimentation. Those features and advancement in liturgiological scholarship brought yet another revision in 1928 (see also COMMON PRAYER, BOOK OF). The 1918 hymnal similarly was superseded by the hymnal of 1940. Acknowledging a continual need to modernize and enrich its worship, the church established a standing committee on prayer book revision.

After World War I also was founded the Church Pension Fund for support of retired clergy and families of deceased clergy. Concern for recruiting and training clergymen increased then and again just after World War II. This interest in education led to raising the number and quality of theological seminaries and to the founding of several ministerial training institutes. Postordination training centres and conferences flourished, especially to spread the church's postwar approaches to Christian education of children and adults; approaches which, embodying insights of modern pedagogy, developmental psychology, and group dynamics, prompted the founding of numerous parochial day schools and increased the church's long-standing efforts in the field of preparatory education. Few colleges, however, are sponsored by the Protestant Episcopal Church. The work of Christian education has emphasized lay participation in church affairs. Thousands of men and women have become church school teachers, and the number of lay readers (men licensed to lead certain aspects of public worship) has surpassed the number of clergymen. Women have maintained their traditional support of missionary endeavours, served on altar guilds, directed programs of Christian education; they may enter religious communities or the order of deaconesses but may not be ordained ministers.

POLITY, WORSHIP, AND DOCTRINE

Polity.—As distinguished from church order, which is threefold and episcopally ordained, the church's polity has been basically congregational with admixtures of presbyterial and episcopal elements. Each self-supporting congregation (parish) elects its lay governing board (vestry) for temporal affairs and its clergyman (rector) as spiritual leader. Except in cases requiring episcopal discipline, tenure of the rector is broken by mutual consent of himself and the vestry. Assistant clergymen (curates, assistant rectors, associate rectors) aid larger parishes. Congregations not self-supporting (missions) fall under the bishop, who appoints lay members to oversee temporal affairs and the clergymen (vicars) for spiritual leadership.

In a given area the parishes and missions federate into a diocese; or, where unable to afford diocesan status of self-support, into a missionary district. All clergymen and representatives of all congregations meet annually in convention to adopt budget and program and to set policy. Each diocese is served by a bishop elected by convention to serve until death or retirement, election being subject to approval by a majority of the other dioceses. There may be assistant bishops as coadjutors (with right and duty of succession) or as suffragans (who may be translated to other dioceses or missionary districts). Most episcopal functions are constitutionally limited by an elected standing committee of laymen and clergymen. The bishop acts, however, in his own right and rarely as representing a *collegium episcoporum*.

The dioceses and missionary districts federate into the General Convention meeting triennially. In its House of Bishops sits each bishop, and in the House of Deputies equal numbers of clergy and laymen representing dioceses and missionary districts. Fundamentally a legislative body, requiring concurrence of both houses for action, the General Convention is related to dioceses and districts as a federal, not a national, organ. Its administrative agency, the Executive Council, is headed by the presiding bishop, who also presides over the House of Bishops. That house meets between conventions largely in an advisory capacity.

Worship and Doctrine.—The Protestant Episcopal Church is a liturgical church whose authorized forms of worship are set forth in the Book of Common Prayer adopted by General Convention. The forms of public worship (morning prayer, evening prayer, litany, Holy Communion) are composed very largely of biblical

material arranged for much congregational participation. The book also provides forms for ordaining deacons, priests, and bishops; for baptism, catechizing, confirmation, matrimony, churching of women, visitation and communion of the sick, burial of the dead, etc. Usual public worship on Sundays is morning prayer or Holy Communion or both, occasionally litany and evening prayer. Morning prayer consists of call to worship; confession and absolution; canticles, psalms, and lessons; stated and variable prayers. Customarily there are added hymns, sermon, offertory, and closing prayers. Holy Communion consists of preparation; collect, epistle, and gospel; creed and sermon (the latter sometimes omitted); offertory of alms, bread and wine, and prayer; confession and absolution; consecration; administration of communion; closing prayers. Hymns are usually added, and often portions of the service are intoned or sung or accompanied by elaborate ritual. Theologically and literarily, the Holy Communion service blends elements of the Protestant Lord's Supper and of the Roman Mass; rubrical latitude allows for ceremonial variations which in actual practice can give either interpretation to this service. Congregation as well as clergyman is assigned definite parts of each service and thus participates in the leadership of, rather than following or listening to, worship. Appropriate postures are assumed for each type of worship activity: kneeling for prayer, standing for praise, sitting for instruction. At each service is prayed the Lord's Prayer, and, except at the litany, either the Apostles' or the Nicene Creed (see CREED) is recited. Scripture readings may be from one of several approved translations and include lessons from the Apocrypha. Public worship is required to be in the vernacular, although its contents are drawn from many eras, languages, and traditions.

The church has inherited its doctrinal formularies from the Church of England but does not apply these statements as rigid confessions. Developing as it did in the context of the Enlightenment's suspicion of strict dogmatism, it has cherished the classic creeds and its changing prayer book as stating its doctrinal position. Baptism and confirmation involve accepting "all the articles of the Christian Faith as contained in the Apostles' Creed." The Nicene Creed is taken to be an adequate summary of belief and thus is recited in public worship, but not, as in the Church of England, the Athanasian Creed. The Thirty-Nine Articles (*q.v.*) of the Church of England, slightly adapted to suit American circumstances, are part of the prayer book and of official doctrine, but formal subscription as such is required neither of clergy nor laity. The prayer book's catechism and offices of instruction are succinct statements of the church's teaching. All these formularies, excepting of course the creeds, bear the unmistakable imprint of the Protestant Reformation. While Scripture is the primary and incontrovertible fountain of doctrine, Anglican tradition appeals also to the early church and to reason. Rather than upon confessions as expressing the whole content of the faith, the church lays emphasis upon not teaching nor believing against Scripture, creeds, and prayer book. Within these limits are held various and often divergent doctrinal and theological opinions both by clergy and laity, some preferring Catholic, some Protestant, some liberal, and some modernist interpretations of the church's basic formularies.

Distinctive Aspects.—Along with other Anglican churches, this church has been distinguished by the richness and dignity of its worship. It has been marked by an ability to hold a full catholic heritage under the control of Reformation principles while opening itself to new intellectual movements, portraying itself as a *via media* between extremes of Roman Catholicism and Protestantism. Engagement in ecumenical discussions has concentrated attention upon the church's preservation of an uninterrupted succession of bishops through the doctrinal and liturgical reform of the 16th century and through subsequent upheavals. From a declaration of the church's General Convention in Chicago in 1886 was formed the "Lambeth Quadrilateral" stating four points upon which Anglicans would enter union negotiations with any Christian body: the Holy Scriptures, the Apostles' and the Nicene Creed, the sacraments of baptism and the Supper of the Lord, and the historic episcopate. The formula has come to be understood as stating the

distinct marks of the church and the communion, but wide acceptance in other communions of the first three points has turned attention to the fourth as a distinctive, but of course not exclusive, possession of this church. Some Episcopalians would insist that no true church exists apart from the historic episcopate in this apostolic succession, while others would hold this feature as a mark of the well-being or fullness, but not of the *esse*, of a true church.

Through membership in the National Council of the Churches of Christ in America and in the World Council of Churches, the Episcopal Church has participated in the movement toward interchurch cooperation and union. Intercommunion with Old Catholics (*q.v.*) has been achieved and has been anxiously sought with Eastern Orthodox and other churches. Unity negotiations with such American denominations as Methodists and Presbyterians have been pursued inconclusively.

(W. A. CL.)

PROTEUS, the prophetic old man of the sea in Greek mythology and shepherd of the sea's flocks (seals, etc.). According to Homer, his dwelling place was the island of Pharos, near the mouth of the Nile; in Virgil his home is the island of Carpathus, between Crete and Rhodes. He knew all things, past, present, and future, but disliked telling what he knew. Those who wished to consult him had first to surprise and bind him during his noonday slumber in a cave by the sea, where he spent his time during the heat of the day surrounded by his seals. Even when caught he would try to escape by assuming all sorts of shapes, that of a lion, a serpent, a leopard, a boar, a tree, fire, water. But if his captor held him fast the god at last returned to his proper shape, gave the wished-for answer and plunged into the sea. He was subject to Poseidon. In post-Homeric times the story (invented by the Greek lyric poet Stesichorus?) ran that Proteus was the son of Poseidon and a king of Egypt, to whose court Helen was taken by Hermes after she had been carried off, Paris being accompanied to Troy by a phantom substituted for her. This is the story followed by Herodotus, who got it from Egyptian priests, and by Euripides in the *Helena*. From his power of assuming whatever shape he pleased, Proteus came to be regarded, especially by the Orphic mystics, as a symbol of the original matter from which the world was created.

PROTEUS (OLM), a blind, aquatic salamander, *Proteus anguinus*, that lives in the dark caves of Yugoslavia and elsewhere in southern Europe. Like its relative the North American mud puppy (*Necturus*), with which it constitutes the family Proteidae, the olm is neotenus; *i.e.*, it is permanently larval and breeds without ever attaining a definite adult stage. The olm attains a length of about a foot; its elongate body is pale except for the carmine red gill plumes (3 pairs). The minute limbs bear three digits on the anterior pair, two on the posterior pair. The head is narrow, with a flat, blunt snout and vestigial eyes covered by opaque skin. Exposure to white light causes the skin to blacken gradually, even over the eyes. See also AMPHIBIA.

PROTHESIS, in the liturgy of the Orthodox Eastern Church, the name given to the act of "setting forth" the oblation; *i.e.*, the arranging of the bread on the paten, the signing of the cross on the bread with the sacred spear, the mixing of the chalice and the veiling of the paten and chalice (Gr. *prothesis*, "a setting forth"). In Eastern Orthodoxy the commoner term for the preparation of these elements is "proskomide." The term is used, architecturally, for the place in which this ceremony is enacted, a chamber on the north side of the central apse in a Greek church; the term is also applied to the small table on which it is done.

During the reign of Justin II (565–578) this chamber was located in an apse and another apse was added on the south side for the diaconicon, so that from his time the Greek church was triapsal. In the churches in central Syria both prothesis and diaconia are generally rectangular, and the former constitutes a chamber for the deposit of offerings by the faithful. Consequently it was sometimes placed on the south side, if when so placed it was more accessible to the pilgrims. There is always a much wider doorway to the prothesis than to the diaconicon. There are cases where a side doorway from the central apse leads direct to the diaconicon, but never to the prothesis.

PROTIC, STOJAN (1857–1923), Serbian statesman and first prime minister of the Kingdom of Serbs, Croats, and Slovenes, was born at Krusevac on Jan. 28, 1857. After studying history and philology in Belgrade, he entered government service but resigned in order to devote himself to journalism. As editor of the Radical daily *Samouprava*, he was imprisoned for a press offense. He edited the paper *Odjek* ("Echo"; 1884), in which he advocated a change of the constitution. Elected to parliament in 1887, he became secretary of the Commission for the Drafting of a Constitution. Between 1888 and 1897, being reelected to parliament, he thrice entered government service, but each time he either resigned or was dismissed as a prominent Radical. He founded the monthly *Delo* ("Deed") in 1894 and was its first editor. After an attempt on the life of King Milan (*q.v.*) he was charged with plotting and was sentenced in 1899 to 20 years' hard labour in fetters, but was reprieved in 1900. Appointed keeper of the National Library he reentered parliament in 1901. Between 1903 and 1918 he was four times home secretary and twice minister of finance.

Protic formed the first cabinet of the Kingdom of Serbs, Croats, and Slovenes on Dec. 20, 1918. He resigned on Aug. 16, 1919, but was prime minister again from February to May 1920. Later he was minister in charge of the constituent assembly and the adjustment of laws. He retired from politics in 1923 and died in Belgrade on Oct. 28, 1923.

From 1903, Protic together with Nikola Pasic (*q.v.*) and Ljazar Pacu (1855–1915) was a member of the triumvirate which *de facto* ruled the Serbian Radical Party. In June 1914, while Pasic the prime minister, was canvassing his constituency, Austria-Hungary delivered the ultimatum which was to start World War I. The ultimatum was handed to the senior available minister, Pacu, but Protic drafted the Serbian reply. In the constituent assembly of 1920–21 he disagreed with Pasic and the Radical Party: his constitutional ideas were based on the English concept of home rule and he advocated them in his new daily *Radikal*. He fought his last election (1923) as an Independent Radical, but neither he nor any of his followers was returned. A distinguished writer, he left a number of works on Balkan political questions. (K. St. P.)

PROTISTA, a third kingdom of organisms, suggested by the German zoologist Ernst Haeckel in 1866 to provide a convenient taxonomic niche for forms intermediate between the animal and plant kingdoms. Many protists are unicellular (or acellular) those few that have more than one cell lack the tissue differentiation characteristic of higher organisms. Included in this group are both animallike and plantlike forms, which, on the basis of relative biological complexity, are divided into (1) lower protists (sometimes called Monera)—the bacteria and blue-green algae and (2) the higher protists—the remaining algae, protozoans, and fungi. The concept of the Protista has not met with complete acceptance by biologists because of the general lack of consensus over where the line should be drawn between protists and higher organisms. See also ALGAE; BACTERIA; FUNGI; PROTOZOA.

PROTOCOL AND PRECEDENCE, two terms frequently used in diplomacy and public affairs, chiefly in regard to formal ceremonies.

Protocol.—In addition to rules governing diplomatic conduct and ceremonies, this term denotes a variety of written instruments. It is applied to the minutes (*procès-verbaux*) of the several sittings of an international conference or congress; though signed by the plenipotentiaries present, these minutes have only the force of verbal engagements (see CONFERENCE, INTERNATIONAL). It is also given to certain diplomatic instruments in

which, without the form of a treaty or convention being adopted, are recorded the principles or the matters of detail on which an agreement has been reached; e.g., making special arrangements for carrying out the objects of previous treaties, defining these objects more clearly, or interpreting the exact sense of a doubtful clause in a treaty. Occasionally an agreement between two or more powers takes the form of a protocol, rather than a treaty, when the intention is to proclaim a community of views or aims without binding them to eventual common action in support of those views or aims.

In the other sense of its meaning, "the protocol" (*protocole diplomatique, protocole de chancellerie*) is the body of ceremonial rules to be observed in all written or personal official intercourse between the heads of different states or their ministers. It lays down the styles and titles of states and of their heads and public ministers, and indicates the forms and customary courtesies to be observed in all international acts. "It is," says P. L. E. Pradier-Fodéré, "the code of international politeness."

Precedence.—To a large extent, protocol is based on rules of precedence: who goes first? who follows whom? Priority of place or superiority of rank has appeared in the hierarchical organization of society throughout the world from the earliest times. During the centuries when feudalism flourished in western Europe a complicated system of precedence developed among the families bound to the royal houses through grants of land in exchange for military service. The titles duke, marquess, count, earl, viscount, baron, and knight were military in origin. Knights, at first cavalymen of the medieval armies, became officers ceremonially created (dubbed), with rank according to the size of their retinue, their prowess, or their membership in one of the religiously inspired orders of chivalry. From the 14th–15th centuries, the kings gradually succeeded in converting them into the modern type of dependent, domesticated nobility, a process made easier by the creation of secular knightly orders constituting an elite of great lustre but without equivalent power. (Some of these orders still survive. See KNIGHTHOOD, CHIVALRY AND ORDERS.) The nobility were thus transformed into sophisticated, modish courtiers, holders of rich sinecures and largely preoccupied with gaining or keeping the personal favour of their monarch. Rigid, meticulous, and glittering ceremonial, designed to reflect the glory of the monarch, was instituted at the permanent royal courts which were being established by the mid-16th century. This system reached its apogee at the Versailles of Louis XIV of France, where the greatest nobles deemed it an honour to assist the king at his rising and retiring.

This way of life came to an end with the Revolution. In modern France the former nobility (who may use their titles socially) have no official place. Precedence on ceremonial occasions is accorded, after the president of the republic, to state, academic, municipal, military, commercial, and legal officials according to their rank, a high place being allotted to the chancellors and officers of the Legion of Honour and the Order of Liberation.

Great Britain and Commonwealth.—The British scales of general precedence may be taken as an example of a modern system of precedence in a monarchical state. Its foundation is the Act of 1539 "for the placing of the Lords in Parliament" (31 Hen. VIII c. 10). The elaborate tables for England, Scotland, and Northern Ireland, separate for men and for women, can be found in *Burke's Peerage* (biennial) and *Debrett's Peerage* (annual).

First comes the crown, the fountain of honour, the symbol of continuity behind changes of government and the main link with the older Commonwealth countries. The royal family is followed in the English scale by the archbishop of Canterbury, the lord high chancellor, the archbishop of York, and the prime minister. (Logically, it might be thought that the prime minister, entrusted as he is by the sovereign with the formation of government, should come first after the royal family. In Canada and New Zealand, the prime minister does come first after the governor-general representing the crown; in Australia he comes next after the governors of the separate states, and in India next after the president.) In the Scottish scale, the lord high commissioner to the General Assembly of the Church of Scotland comes next after

the sovereign and the sovereign's consort while the Assembly is in session. The moderator comes immediately before the prime minister. Most of the Commonwealth countries admit to their scales the leaders of all the principal denominations.

In England it is worthy of note that holders of ceremonial offices, such as the lord high treasurer, may precede holders of important government posts, such as the speaker of the House of Commons. Some offices of great importance have a comparatively lowly place in the scale. The chancellor of the exchequer is probably second only to the prime minister in importance in the cabinet; and the lord chief justice is the embodiment of the majesty and power of the law; yet both are ranked after the vice-chamberlain of the household. Among the orders and decorations there are similar anomalies. The highest qualifications are needed for the Order of Merit. Yet it has no place in the scale. The Distinguished Service Order is admitted, but the Victoria Cross, the most highly prized of all military awards, is excluded. Indeed the fighting forces as such have no position in the English scale of general precedence. The anomalous situation with regard to precedence of admirals of the fleet, field marshals, and marshals of the Royal Air Force is concealed by conferring peerages or knighthoods upon the most eminent of them.

The English scale takes no account of local precedence; the lord lieutenant of a county, for example, finds no place. And the precedence of lord mayors and mayors is confined to their cities and boroughs and to their year of office.

The strictly aristocratic and hereditary elements in the scale come in the following order: dukes, marquesses, earls, viscounts, barons; with their wives, sons, daughters, and grandchildren. (See also PEERAGE.) It may be important to know, upon ceremonial or social occasions, that the eldest son of an earl comes before the younger son of a marquess. It is all very exact but somewhat remote and antiquated because precedence does not reflect the lords' loss of direct political power or their loss of wealth.

There are also "courtesy" titles, which confer no precedence. They arise because each of the higher peers has one or more subordinate titles lower in degree than that generally used. It is customary to address the eldest son of such a peer by his father's second title; so that the eldest son of the duke of Bedford, for instance, is known as the marquess of Tavistock. But the marquess is not a peer, does not sit in the House of Lords, and takes precedence only derivatively as the son of his father.

The tables of precedence of the older Commonwealth countries, though giving, of course, first place to the representative of the sovereign, follow the U.S. model (see below) much more nearly than the British. India, as a federal republic, has a table in which the president is followed by a complex sequence of officials and former officials of the Indian union and states and high-ranking officers of the armed forces. (X.)

United States.—Precedence at official functions and ceremonies in the United States is based upon official position and custom. The latter, outside of Washington, D.C., reflects the social and economic variables found in state and local communities on official occasions, and these affect strictly official considerations in the order of precedence in terms of religion, wealth, and other factors determining civic status. Political expediency rather than statutes prevails in the determination of the hierarchical order in public ceremonies. The tendency toward informality at state and municipal functions is in sharp contrast with the more ostentatious public affairs of the 19th century.

Washington, D.C.—Precedence in the capital of the U.S. is subject to a combined governmental and diplomatic ranking of which the Department of State is the arbiter. The division of protocol not only rules on official ranking, but informally provides essential guidance for social functions where official status at the national or international level is involved.

Precedence has been established by custom as:

The president; vice-president; speaker of the House of Representatives; chief justice of the United States; former presidents; secretary of state; ambassadors of foreign powers, ranked according to diplomatic rule of seniority by the date of presentation of credentials; widows of former presidents; secretary-general of the United Nations; U.S. representative to the UN; ministers of foreign powers in order of diplo-

matic seniority; associate justices; president's Cabinet (secretary of state excepted), in order of establishment of their offices: secretary of the treasury, secretary of defense, attorney general, postmaster general, secretaries of the interior, agriculture, commerce, labour, and health, education and welfare; senators; governors of states; former vice-presidents; members of the House of Representatives; *chargés d'affaires* of foreign powers; undersecretary of state; undersecretaries and deputy secretaries of the executive departments; secretaries of the Army, Navy, and Air Force; director, Bureau of the Budget; chairman, Council of Economic Advisers; chairman, Board of Governors of the Federal Reserve System; chairman, Joint Chiefs of Staff; chief of staff of the Army, chief of naval operations, and chief of staff of the Air Force; generals of the Army and fleet admirals; director, Central Intelligence Agency; director, U.S. Information Agency; administrator, National Aeronautics and Space Administration; and heads of other agencies.

Generally speaking, the states of the union follow a rule-of-thumb order of precedence on official occasions. Reception and seating depend upon the obvious political ranking and the expedient religious, economic, and social considerations in a given situation involving status. This situation has been facilitated by a departure from large, formal state affairs with a trend toward informality in official entertainment.

U.S. cities set up their own protocol for the reception of distinguished visitors. This follows a general political pattern of officials, headed by the mayor or his equivalent in other types of urban government or his representative for the occasion. Precedence again is weighed in terms of religious and civic status; it is flexible in its application in order to permit adjustments suitable for each function.

After World War II the increasing number of foreign visitors to the U.S. with official or quasi-official sponsorship made strategically located cities important points of reception. Chief of these is New York City, where the mayor's office has special machinery for extending such hospitality to visitors. The commissioner of commerce and public events is charged with all arrangements; an officer under him works out the problems of reception and precedence. This official is in contact with the State Department and the visitor's diplomatic mission in Washington or local consular representation; where the visitor's status warrants extensive ceremonies—a chief of state, head of government, etc.—these are planned by close consultation as to details of time, place, and guest list.

(Cs. H.)

Communist Countries.—In the U.S.S.R. and other republics of eastern and southeastern Europe, the first secretary of the Communist or Workers' (*i.e.*, ruling) Party takes precedence over all and is followed by the premier. Next comes the chairman of the Presidium of the Supreme Soviet (U.S.S.R.); the chairman of the Council of State (Poland); the president of the Presidential Council (Hungary); etc.

(X.)

Diplomatic Corps.—As many ceremonies of state involve the diplomatic corps, diplomats occupy a prominent position in social life. The practice of diplomacy, which had occasioned many unseemly disputes (notably that between the Spanish and French ambassadors in London in 1661) was regularized by the decrees of the congresses of Vienna (1815) and of Aix-la-Chapelle (1818) on an agreed basis.

Four categories of representatives were recognized: (1) ambassadors, legates, or nuncios; (2) envoys extraordinary and ministers plenipotentiary; (3) ministers resident; (4) *chargés d'affaires*. Precedence within the corps was established on the basis of seniority of appointment, so that the doyen (or dean) of the corps is that ambassador who has been accredited to his post the longest; *i.e.*, from the date of his official arrival and presentation of his letters of credence. In most Roman Catholic countries where the church enjoys a special position, the papal nuncio takes precedence over all his colleagues regardless of the date of his appointment. Even in this case, however, the senior ambassador continues to discharge most of the functions of the doyen. For consular officers (consuls general, consuls, vice-consuls, and consular agents) there is a comparative precedence which equates them with certain ranks of the fighting services. Thus consuls general rank with but after rear admirals, major generals, and air vice-marshals, while consuls rank with but after captains of the Royal Navy, colonels, and group captains of the Royal Air Force. In monarchical countries ambassadors usually have precedence

after members of the reigning family or high dignitaries of church and state. In England they follow the lord privy seal, while ministers come after dukes but before marquesses. In republics, practice varies: thus in France ambassadors come after the presidents of the Senate and of the National Assembly, whereas in the United States they come after the vice-president and before the chief justice.

(S. B.-R. P.)

United Nations.—Precedence is a matter wholly determined by the UN itself in governing its procedures, ceremonies, and social functions. Directly under the secretary-general there is a unit at the headquarters to handle problems of precedence similar to that in any foreign office, the chief and assistant chief of protocol. Here all UN precedence, whether procedural, ceremonial, or social, is determined. There are no hard-and-fast rules nor is there an official list. Precedence is a developing process which combines regulations for the functioning of UN bodies, their officials, and representatives of member states with appropriate diplomatic conventions currently prevalent in international intercourse.

Basically, UN precedence rests on function and not upon the personal rank of the person discharging the duty. Hence the president of the General Assembly, irrespective of the delegate's personal rank, is the ranking official of the UN when the assembly is in session. The president of the Security Council, the second most important organ in terms of the Charter, becomes the chief functionary in terms of protocol if the assembly is not in session. However, since the headship of the Security Council rotates each month among the members, the person enjoying this prerogative changes accordingly.

The third post is that of the secretary-general, the executive-administrative officer of the UN who heads the Secretariat. Then follow the presiding officers of the specialized organs of the UN, the Economic and Social Council, the Trusteeship Council, etc., when in session; the heads of the permanent delegations accredited by the member states to the UN of ambassadorial rank; the assistant secretary-general and the undersecretaries; heads of delegations of ministerial rank; the operating heads of the departments into which the secretariat is subdivided.

The diplomatic practice that ambassadors and ministers rank according to the date of their appointment is not followed at the UN; strict observance of the alphabetical order of the countries they represent is the rule in session and elsewhere. In sessions of the UN organs, the actual seating facilities of the chambers used at headquarters, at Geneva, Switz., and elsewhere affect the working out of precedence for those occupying places on the rostrum; the alphabetical order in general seating of delegates on the floor rotates from front to rear so that the position of a member state's spokesman moves progressively, meeting by meeting, and no country enjoys a preferred position by reason of its name.

(Cs. H.)

Roman Catholic Church.—The Roman Catholic Church, transcending all national boundaries, has its own hierarchy, or governing body, whose precedence is as follows: the pope; the Sacred College of Cardinals; archbishops and bishops; delegates, vicars, and prefects apostolic; certain abbots and prelates. Lower clergy also are strictly ranked, from provosts and vicars general of dioceses to assistant priests (*curates*). Precedence within these grades is, generally speaking, by date of election to them.

Normally, secular (*i.e.*, diocesan) clergy have precedence at ceremonial functions over regular clergy (*i.e.*, members of religious orders). However, religious superiors, *e.g.*, fathers general provincial, etc., are customarily granted special places in accordance with the occasion and circumstances.

(X.)

Tendencies of the 20th Century.—As the prevailing policy of the 20th century favours republican forms of government, questions of precedence occupy less attention than heretofore. Even in the few remaining monarchies rank and title possess less significance than before. Thus in Denmark and in Norway all titles have long been abolished. In Japan all titles of nobility were abolished and the house of peers was replaced by a house of councillors in 1945; and the imperial house law of 1947 restricted the emperor's family to his children, his brothers and sisters, and their

issue, with the result that 51 princes of 11 princely houses became commoners. Most modern orders (for example the Legion of Honour in France and the 16 orders created in the U.S.S.R.) do not entitle the recipients to any privileges but are simply marks of recognition of merit and service.

The 17th and 18th centuries were the golden age of court ceremonial; cf. the *Mémoires* of the duc de Saint-Simon. Since that time the importance of questions of precedence has grown less and less. The emphasis has altered from rank and title to office and position. It is in fact a person's office rather than his personal rank or his relationship to someone else that now tends to be the governing factor in determining his precedence. (S. B.-R. P.)

PROTOGENES, a Greek painter, born in Caunus, on the coast of Caria, but resident in Rhodes during the latter half of the 4th century B.C. He was celebrated for the minute and laborious finish which he bestowed on his pictures, both in drawing and in colour. Apelles, his great rival, standing amazed in the presence of one of these works, could only console himself by saying that it was wanting in charm. On one picture, the "Ialysus," Protogenes spent seven years; on another, the "Satyr," he worked continuously during the siege of Rhodes by Demetrius Poliorcetes (305–304 B.C.), notwithstanding that the garden in which he painted was in the middle of the enemy's camp. Demetrius, unsolicited, took measures for his safety; more than that, when told that the "Ialysus" just mentioned was in a part of the town exposed to assault, Demetrius changed his plan of operations. Ialysus was a local hero, the founder of the town of the same name in the island of Rhodes, and he was probably represented as a huntsman. This picture was still in Rhodes in the time of Cicero, but was afterward removed to Rome, where it perished in the burning of the Temple of Peace.

The picture painted during the siege of Rhodes consisted of a satyr leaning idly against a pillar on which was a figure of a partridge, so lifelike that ordinary spectators saw nothing but it. Enraged on this account, the painter wiped out the partridge. The "Satyr" must have been one of his last works. He would then have been about 70 years of age, and enjoyed for about 20 years a reputation next only to that of Apelles, his friend and benefactor. Both were finished colourists so far as the fresco painting of their day permitted, and both were laborious in the practice of drawing, doubtless with the view to obtaining bold effects of perspective as well as fineness of outline. It was an illustration of this practice when Apelles, finding in the house of Protogenes a large panel already prepared for a picture, drew upon it with a brush a very fine line which he said would tell sufficiently who had called. Protogenes on his return home took a brush with a different colour and drew a still finer line along that of Apelles, dividing it in two. Apelles called again, and thus challenged, drew with a third colour another line within that of Protogenes, who then admitted himself surpassed. This panel was seen by Pliny in Rome, where it was much admired, and where it was destroyed by fire.

In the Propylaea at Athens was a painting by Protogenes representing personifications of the coast of Attica, Paralus, and Hammonias. For the council chamber at Athens he painted figures of the Thesmoethetae, but in what form or character is not known. Probably these works were executed in Athens, and it may have been then that he met Aristotle, who recommended him to take for subjects the deeds of Alexander the Great. In his "Alexander and Pan" he may have followed that advice in the idealizing spirit to which he was accustomed. To this spirit must be traced also his "Cydippe" and "Tlepolemus," legendary personages of Rhodes. Among his portraits are mentioned those of the mother of Aristotle, Philiscus, the tragic poet, and King Antigonus. Protogenes was also a sculptor to some extent, and made several bronze statues of athletes, armed figures, huntsmen, and persons in the act of offering sacrifices.

PROTON, a particle which is the nucleus of the hydrogen atom and a constituent of the nuclei of other atoms. It carries a positive electric charge.

Historical Background.—Lord Rutherford, in the course of experiments performed in 1919 during which he bombarded atoms of the lighter gases with alpha particles, found that the atoms disintegrated under the impact, liberating particles that he believed to be hydrogen nuclei. At the Cardiff meeting of the British Association for the Advancement of Science (1920), Rutherford suggested the name proton—Greek for "the first"—for the nucleus of the hydrogen atom, to denote that it is a primary substance. In the same year, in the Bakerian lecture at the Royal Society, he offered the speculation that there might exist yet another particle, this one electrically neutral. This hypothetical particle—the neutron—was brought from the realm of speculation to reality in 1932 by a succession of discoveries by W. Bothe, Frédéric Joliot, and Sir James Chadwick, who made the decisive experiments. The nuclei of all atoms except hydrogen contain neutrons as well as protons. In the case of hydrogen, the atom consists of a single proton as the nucleus, plus a single electron.

Characteristics.—The main properties of the proton are its electric charge, mass, spin, magnetic moment, and statistics. The charge, e , is identical in magnitude to the charge of the electron, 4.80298×10^{-10} esu (electrostatic units), but of opposite sign; and the mass of the proton is 1.6725×10^{-24} g. This is 1,836.1 times as large as the mass of the electron. It is thus apparent that almost the entire mass of an atom is concentrated in the nucleus. The equality in magnitude of the charge of the proton and of the electron is shown by the fact that hydrogen atoms are neutral; hence, in order to know the charge e it makes no difference whether one measures the charge of the proton or of the electron. The latter is perhaps technically easier to measure. The mass of the proton may be determined by mass spectrograph experiments involving the deflection of a beam of protons of known velocity in a known magnetic field. In this way one obtains a measurement of the momentum mv of the proton which, once the velocity v is separately measured, gives the mass m .

In addition to charge and mass, the proton has an intrinsic angular momentum or spin of magnitude $\frac{1}{2}h/2\pi$ where $h = 6.6256 \times 10^{-27}$ erg-sec. (Planck constant). If we visualize a proton as a little sphere of matter, the spin tells us that the proton is rotating around an axis in a way similar to the rotation of the earth around the polar axis. The proton spin is revealed by a detailed study of the hydrogen atom spectrum and by many other phenomena. Connected with the spin there is a magnetic moment $\mu_p = 1.41049 \times 10^{-23}$ erg per gauss. In terms of the natural unit $he/4\pi m_p c$ (where m_p is the mass of the proton and c the velocity of light), this moment has the value 2.79276. This means on our model that the small rotating sphere also has north and south magnetic poles similar to those of the earth. The magnetic moment of the proton, and its spin, can be measured spectroscopically or, with extreme precision, by magnetic methods involving the currents induced by the nuclear magnetic moments of the protons moving in a variable magnetic field. The size of the proton (or its radius, if we consider it as a sphere) is not precisely defined because its value depends on what phenomenon or method we use to measure it. For instance, by bombarding the protons with high-energy electrons (up to 10^{10} ev) one obtains a pattern that reveals the distribution of the electric charge around the centre of the proton (Robert Hofstadter). One thus obtains an average radius of 1.2×10^{-13} cm. There are indications that the proton has a structure consisting of a core surrounded by a cloud of mesons. A similar structure obtains also for the neutron. An important part of the specific nuclear forces originate from an exchange of the pions of the cloud between different nucleons (*i.e.*, neutrons and protons). The radius of the proton can also be investigated by neutron-proton collision at high energy in which only specific nuclear forces are operative. The results resemble those obtained by electron scattering.

In addition to the properties mentioned above, the proton has a very important characteristic which is expressible only in terms of quantum mechanics: it obeys Pauli's exclusion principle. This

can be expressed by saying that in a system there cannot be two or more protons with the same quantum numbers, or that the wave function of a system containing several protons must be antisymmetrical with respect to the exchange of any two protons. This property has far reaching consequences in nuclear structure and is one of the most fundamental ones shared by proton, neutron, electron and other particles having spin $\frac{1}{2} \hbar/2\pi$. A nucleus of mass number A having a positive electric charge Ze contains Z protons and has a number of neutrons N given by the number $A - Z$. A is the integer closest to the number expressing the nuclear mass M in units equal to the 12th part of the mass of the carbon nucleus C^{12} .

The Proton in Theoretical and Applied Science.—The proton appears in many different aspects in a variety of chemical and physical phenomena. For example, as the hydrogen ion, it plays a very important role in chemistry, especially in all aqueous solutions (see HYDROGEN IONS). In spectroscopy it is the centre around which the electron revolves in the hydrogen atom, giving rise to the hydrogen spectrum, one of the most important subjects in atomic physics. In nuclear physics the proton is commonly used as a projectile to bombard other nuclei in particle accelerators such as the cyclotron or the bevatron.

In nuclear bombardments at relatively low energies, up to a few million electron volts, the general behaviour of the proton is to enter the nucleus, if it has enough energy to overcome the electrostatic repulsion of the target nucleus. Having entered the target nucleus it produces enough excitation to evaporate other particles from it. For instance if it evaporates one neutron, the target nucleus does not change its mass number, but is transformed into an element with the atomic number, (Z) one unit larger.

At very high energies the proton gives rise to a host of more complicated effects connected with the structure of the nucleons. Especially relevant to the proton is the existence of excited states of this particle that decompose into a proton in its normal state and a pi-meson (pion). The most prominent of these states has a total energy (including that due to the rest mass) of about 1,238 Mev, and spin $\frac{3}{2}$. It is excited by pion or by other particle bombardments. It is by proton bombardments that mesons, hyperons and antinucleons are most frequently produced in the large accelerators.

The number of protons, plus the number of neutrons involved, remains constant in all nuclear reactions. This principle of the conservation of the nucleons is at present to be considered as an empirical fact still disconnected from the other fundamental principles of physics.

P. A. M. Dirac of England pointed out in 1928 that the phenomena of nature exhibit a special kind of symmetry between the positive and negative electric charge. On this basis he predicted the possible existence of the positive electron (positron), later discovered (1932) by C. D. Anderson. Dirac's theory predicted also the possible existence of a negatively charged proton (antiproton) which was discovered in 1955 by Owen Chamberlain, Emilio Segrè, Clyde Wiegand, and Thomas Ypsilantis. The theory predicted the following properties for this particle: (1) it has the same mass as the proton; (2) it has equal but opposite electric charge; (3) it has the same spin as the proton; (4) it has a magnetic moment opposite to that of the proton; (5) it is stable in the sense that when isolated in a vacuum it does not transform spontaneously into other particles; (6) antiprotons and nucleons annihilate each other in pairs; (7) antiprotons and protons are generated in pairs.

Property (4) means that a proton and an antiproton having their spin equally oriented have opposite magnetic moments, or that if the two small rotating spheres representing them rotate in the same way, their magnetic north and south poles are interchanged.

Properties (6) and (7) are not in contradiction with the principle of conservation of nucleons. On the contrary, if we consider an antiproton as "minus one proton," the condition that generation and annihilation occur only in pairs becomes a direct consequence of the conservation of nucleons. The fact that one antiproton and one proton must be generated together determines

the energy threshold for this process. Thus, for instance, the production by proton-proton collision can occur only at a projectile energy higher than 5.6×10^9 ev (electron volts) in the laboratory system; hence, huge accelerating machines are necessary. Antineutrons are characterized by a set of properties which bear a relation to those of the neutron similar to those listed above for the antiproton in relation to the proton. In particular properties 1, 2, 4, 6, 7 are the same provided the word neutron is substituted for proton and antineutron for antiproton. Neutron and antineutron are both electrically neutral and both spontaneously undergo a beta decay, the neutron emitting electrons, the antineutron positrons.

Antineutrons have been generated from antiprotons by causing the antiproton to collide with a proton. In this process most frequently the proton and antiproton annihilate each other, generating pi-mesons, but in about 1% of the cases they disappear, generating a neutron-antineutron pair. The antineutron is best detected in the subsequent annihilation process with a nucleon.

The symmetry between positive and negative electricity manifested by the electron and positron, and nucleon and antinucleon opens the possibility of the existence of "antimatter." This would be formed by atoms in which every nucleon is replaced by the corresponding antinucleon and every electron by a positron. In many ways this antimatter would be indistinguishable from ordinary matter. For example, no ordinary astronomical observation, including the study of the spectra and of the Zeeman effect, could distinguish between matter and antimatter in a star. However, a collision of matter and antimatter would result in annihilation with the immediate production of pi-mesons which would in turn decay, leaving as their ultimate residue gamma rays, neutrinos and, if the system is not initially electrically neutral, electrons.

As of the 1960s there was no experimental evidence in favour of or against the existence of antimatter in the cosmos. From a cosmic point of view the existence of antimatter would allow the creation of the universe from energy without the violation of the principle of the conservation of nucleons.

PROTOPLASM, the characteristic organized substance on which all activities of living matter are based. The cell is the smallest structural unit of protoplasm that has all the properties essential for its maintenance (irritability, motility, and basic metabolism) and propagation (growth and reproduction).

The physiology of protoplasm is highly complex, and is believed to be largely dependent on the properties of colloidal systems. Physical and cytochemical methods of studying living cells, in conjunction with biochemical studies on isolated protoplasmic structures, have revealed the functions of this vital organization (see CELL). Evidently the nucleic acids are ultimately responsible for the pattern of dynamic organization throughout the protoplasm (see NUCLEIC ACIDS).

See also references under "Protoplasm" in the Index. (D. T. H.)

PROTOPOPOV, ALEKSANDR DIMITRIEVICH (1866?–1918), Russian statesman, minister of the interior during the last months of the imperial regime, was a landowner and industrialist who began his political career in the Simbirsk province. He was elected in 1907 to the third duma, where he joined the left wing of the Octobrist Party. In 1914 he became one of the deputy speakers of the fourth duma; and in 1916, during World War I, he led a parliamentary delegation to Great Britain, France and Italy. On his homeward journey he had talks in Stockholm with a German agent on the prospects of a separate Russo-German peace. The misgivings which this indiscretion aroused among the Russian public were intensified when, through Rasputin (q.v.), he was appointed minister of the interior in the reactionary cabinet of B. V. Stürmer (Oct. 1, 1916). His former colleagues in the duma angrily condemned him as a renegade. Protopopov

had always been highly strung, and his advent to power seems to have unhinged his mind. Convinced that it was his destiny "to save Russia," he devised schemes for the social and political reconstruction of the country on totalitarian lines, which his cabinet colleagues dismissed as impracticable fantasies. More concretely, Protopopov urged the dissolution, or at least the suspension, of the duma and changes in the supply organization to enhance the powers of his own ministry as against those of the *zemstva* (the elected local councils) and other public bodies. His measures failed to relieve the serious food shortage in Petrograd and other cities; and when he ordered severe police measures as a precaution against possible hunger riots, he was widely suspected of seeking to provoke a popular rising. Yet when this rising occurred, it brought the overthrow of the regime and Protopopov's own downfall: after the revolution of March 1917 he was imprisoned in the Peter and Paul Fortress and in September 1918 he was shot there by order of the Communist *Cheka* (Extraordinary Commission). (J. L. H. K.)

PROTOZOA, a worldwide phylum of lower animals, most of which are microscopic. Protozoa, almost as ubiquitous as bacteria, are found wherever there is moisture enough for active life. The phylum is abundant in species—more than 30,000; as individuals their numbers far exceed those of any other animal group. The reader should not be dismayed at finding disagreements between classifications of Protozoa, for authorities differ considerably in the disposition of this phylum. A time-honoured scheme divides the group into four subphyla: Mastigophora, the flagellates or whip bearers; Sarcodina, the amoeboid species, with pseudopodia; Sporozoa, the parasitic types that often produce spores; and Ciliophora, the ciliates, equipped with cilia or their derivatives. I. GENERAL FEATURES

The variety of form is endless, from the flowing, protean blobs of amoebas to the exquisitely fashioned "sunbursts" of radiolarians and the delicate shells of foraminifers. The range in size is considerable, from the smallest sporozoan blood parasites (*Babesia*) only 2 microns long (a small red blood cell can easily contain a dozen such organisms) to the largest, also a sporozoan (*Parospora gigantea*), which may reach 16 mm. in length (mycetozoan plasmodia, which are multinucleate amoeboid organisms, may measure 30 cm. or more).

Although protozoans are often described as one-celled animals, some protozoologists prefer to think of them as being noncellular,

or acellular. The simplest protozoans, comparable in structure to a cell of higher animals, contain only a nucleus and the usual cytoplasmic inclusions (mitochondria, stored food, etc.). More complex species may be equipped with many nuclei, a variety of locomotor and feeding organelles, sometimes with involved fibrillar systems and contractile elements.

Many Protozoa seem to be as closely related to plants as to typical animals. For example, certain phytoflagellates form an apparently continuous series with typical algae. The slime molds are claimed by botanists as well as by zoologists. Accordingly, the protozoologist's concept of the phylum Protozoa is based in part upon arbitrary decisions that may or may not reflect the true relationships of the organisms involved. To this extent, the phylum represents a somewhat artificial assemblage rather than a phylogenetically homogeneous group.

II. NATURAL HISTORY

1. Modes of Living.—Many free-living protozoans are motile; others are sessile or floating. Most species exist as solitary forms, but some form colonies. Parasitic protozoans live in or on a variety of organisms, from plants to a wide range of animals including other protozoans. A number of species serve as decom-

posing organisms, hastening the decay of organic matter, whereas several are agents of disease: e.g., those causing malaria, amoebic dysentery, and African sleeping sickness.

Protozoa occur in many relatively pure waters, fresh or salt, containing little organic matter; in waters polluted with material undergoing decomposition; in films of moisture on soil particles, or on particles of sand along beaches; and in body cavities or tissues of their hosts. The species making up a local fauna vary both qualitatively and quantitatively from one environment to another. Such relationships involve, among other factors, the kinds and amounts of food and the methods of feeding in Protozoa.

Protozoan colonies usually contain similar organisms bound together in some particular pattern. A secreted matrix binds the organisms together in various flagellates (*Gonium*, *Volvox*, etc.) and in such ciliates as *Ophrydium*. These colonies are often spheroid or discoid. Other colonies are held together by branching stalks, by a branching exoskeleton (lorica), or by attachment of individual loricae in a branching pattern (e.g., *Hyalobryon*). The *Volvox* colony is unusual in that the component zooids are differentiated into many somatic and a few reproductive individuals.

Aggregates that are not true colonies occur in certain species in which separation of daughter organisms does not promptly follow fission. Such aggregates include chains (catenoid "colonies") of certain dinoflagellates and ciliates and also palmella stages in certain phytoflagellates, similar to spheroid colonies but with an amorphous matrix and without flagella or specific form and size. The term "gleocystis stage," is sometimes applied to similar groupings with a differentiated layer around each organism.

2. Nutrition.—Protozoan nutrition is of two basic types: holozoic, by active ingestion; and saprozoic, by absorption.

Ingestion.—The feeding method of holozoic Protozoa involves ingestion of solids through a permanent or temporary cytostome. Food may be ingested by pseudopodal engulfment (as in *Amoeba*), by confluence of myxopodia to trap prey outside the test (in certain foraminifers), or through a cytopharynx (ciliates). Ciliates often have a buccal cavity (or peristome) equipped with organelles for propelling food to the mouth (cytostome) at the base of the pouch or trough. Such a feeding apparatus is common in ciliates that eat bacteria or other small particles. Many carnivorous ciliates, normally ingesting fairly large prey, have a cytostome opening directly onto the surface rather than into a buccal cavity. In such cases the wall of the cytopharynx may be strengthened with rodlike trichites. The food is enclosed in a vacuole, the wall of which is derived from the surface of the body (*Amoeba*, etc.) or from the lining of the cytopharynx (ciliates). The contents of the food vacuole typically become acid, although the origin of the acid is undetermined. Enzymes presumably are secreted into the vacuole. Digestion follows, and the products are absorbed.

Absorption.—Saprozoic (or osmotrophic) feeding involves absorption of dissolved materials through the pellicle and plasma membrane. To what extent this represents simple diffusion or less passive mechanisms involving enzymatic activity remains uncertain. Pinocytosis, a peculiar process of "drinking," first described in certain amoeboid species, involves ingestion of solutions in gulps through small temporary "gullets," from the inner ends of which vacuoles are pinched off into the cytoplasm. Measurements recorded over short intervals suggest that fluid taken in by an amoeba may amount to at least twice the organism's body volume in a day. In a nutrient-rich medium this could represent a significant contribution to nutrition.

3. Food Requirements.—Since the advent of pure cultures and reasonably pure organic nutrients, it has been possible to

(LEFT) ROMAN VISHNIAC; (RIGHT) PHILIP FEINBERG, FELLOW OF THE NEW YORK MICROSCOPICAL SOCIETY

TWO EXAMPLES OF INGESTION IN PROTOZOA: (LEFT) AMOEBA ENGLUING A VOLVOX COLONY; (RIGHT) EUPLOTES DIGESTING ALGAE (MOVEMENT OF CILIA HAS STARTED A WHIRLPOOL OF ALGAE AT RIGHT)

define rather accurately the food requirements of various protozoans.

In flagellates with chromatophores the need for a chemical source of energy (fatty acid, alcohol, carbohydrate, etc.) may be eliminated by photosynthesis. Many photosynthetic flagellates, when exposed to light, can grow in simple media containing inorganic salts and one or two vitamins. A nitrate or an ammonium salt can supply the needed nitrogen, while carbon dioxide provides the necessary carbon. Other needed elements are available in solution in the medium. Although actual requirements are not completely known, elements supposedly needed by one protozoan or another include calcium, cobalt, copper, iron, magnesium, manganese, phosphorus, potassium, sulfur, and zinc. In addition, growth of certain species is stimulated by aluminum, barium, boron, iodine, silicon, sodium, and vanadium. Photosynthetic flagellates can survive in relatively pure waters, their numbers being limited perhaps by available concentrations of minerals and vitamins (e.g., B₁₂, thiamine). Pollution of waters with material containing large amounts of vitamins, stimulatory organic foods, or minerals (e.g., phosphates) may lead to population bursts or "blooms" of phytoflagellates.

Organisms without chromatophores require a chemical source of energy. Some of the colourless phytoflagellates thrive on such energy sources as acetate, pyruvate, or ethanol, but derive little or no benefit from carbohydrates, possibly because these organisms lack a particular enzyme (hexokinase). There are obvious differences in complexity of food requirements. Some of the saprozoic phytoflagellates, except for the energy source, have basal requirements similar to those of related green species. Other groups of saprozoic Protozoa may have food requirements comparable to those of ciliates and other holozoic types. Holozoic organisms apparently can use a wider variety of energy sources than saprozoic types.

Protein Metabolism.—Holozoic Protozoa, under natural conditions, obtain their proteins mostly in the form of other microorganisms. Certain saprozoic Protozoa (e.g., *Leishmania*) apparently produce extracellular protein-splitting (proteolytic) enzymes; the value of proteins as sole nitrogen sources for these organisms is uncertain. *Tetrahymena pyriformis*, a typical holozoic organism, is known to produce two kinds of proteolytic enzymes (proteinases and peptidases). Amino acids, liberated by these enzymes, may be assimilated directly or may be further broken down by other enzymatic mechanisms. In a medium containing 11 essential amino acids *T. pyriformis* assimilates 5 of them and synthesizes at least 7 additional amino acids, using 5 of the original 11 as raw materials as well as "fuel" for the process of assimilation and for the production of proteins. Phytoflagellates may use ammonium salts or, less commonly, nitrates.

The major nitrogenous waste is ammonia, although more complex materials are sometimes eliminated. *Tetrahymena pyriformis* apparently excretes amino acids (glycine, glutamic acid,

BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY
GLASS MODEL OF A VOLVOX COLONY

etc.) as well as ammonia. The occurrence of a urea cycle in *T. pyriformis*, similar to that of mammals, has been disputed.

Carbon Metabolism.—Photosynthetic flagellates may obtain their needed carbon as carbon dioxide. Green flagellates maintained in darkness, as well as all other Protozoa, need one or more organic compounds in addition to carbon dioxide, the organic compound serving as a source of energy and metabolites for synthesis. Radioactive carbon, fed to *Tetrahymena* in carbon dioxide, becomes incorporated in succinic acid and, in lower concentrations, in certain amino acids (alanine, glycine, aspartic, and glutamic acids) and in other metabolites (fumaric, lactic, malic acids, etc.). Under similar conditions, *Euglena gracilis* in darkness produces essentially the same tagged metabolites, with the addition of certain intermediates in carbohydrate metabolism. In addition to utilizing carbon dioxide, Protozoa as a group can use carbon sources ranging from acetic acid to polysaccharides. However, the ability to use particular compounds varies with the species. Cellulase activity has been reported in certain ciliates from the intestinal tract of ruminants and flagellates from termites. Enzymes digesting starch and glycogen to simple sugars also have been demonstrated (e.g., *Trichomonas*, *Tetrahymena*).

Metabolism of simple sugars follows pathways known in other microorganisms and in higher animals. According to the Meyerhof-Emden scheme of fermentation, glucose and other simple sugars are converted into fructose-diphosphate and eventually broken down, mostly to pyruvic acid, from which Protozoa may produce a variety of materials—carbon dioxide; water; ethanol; acetic, formic, lactic, and succinic acids—depending upon the species. In the phosphogluconic acid route, glucose is phosphorylated to a sugar-monophosphate and then, with a loss of carbon dioxide, converted into a pentose-monophosphate. This pentose may be converted into other pentoses, used in synthesis, or split into products that can be used as energy sources or as intermediates in biosynthesis. In several species (e.g., *Trichomonas vaginalis*) sugar metabolism differs in details. Although extensive information is available for only a few species, it is clear that products of glucose metabolism can vary even among species of a single genus (e.g., *Trypanosoma*). Synthesis of carbohydrates is very common, probably universal in Protozoa. Many species synthesize polysaccharides and store them.

Vitamin Needs.—Most Protozoa need one or more vitamins. Certain green flagellates (e.g., species of *Chlamydomonas* and *Chlorogonium*) require no outside source of vitamins when exposed to light; such species may be considered photoautotrophs in the classical sense—organisms capable of utilizing the energy of sunlight as do green plants. For other green flagellates, one or more vitamins (B₁₂, thiamine, sometimes biotin) must be added to media that are adequate for photoautotrophs. Similar differences are known for colourless phytoflagellates. Certain species of *Polytoma* apparently need no vitamin supplements. Other colourless phytoflagellates, like many of their green relatives, need one to several vitamins. Outside the phytoflagellates, Protozoa have multiple vitamin requirements. Certain strains of *Tetrahymena pyriformis*, for example, must have biotin, folic acid, nicotinic acid, pantothenic acid, pyridoxine, riboflavin, thiamine, and thiocetic acid (protogen).

The knowledge of vitamin requirements has made possible the utilization of Protozoa in biological assays. The choice of organisms is determined by such practical matters as rate of growth and suitability for spectrophotometric measurement of growth. Vitamin B₁₂ has been assayed, even in body fluids, with *Euglena gracilis* and with *Ochromonas malhamensis*, the former being a very sensitive indicator but slightly less specific than the latter in that it responds to pseudo-B₁₂ compounds as well. *Ochromonas malhamensis* also is a sensitive assay organism for thiamine in body fluids, while thiocetic acid can be assayed with *Tetrahymena pyriformis*.

4. Oxygen Requirements.—There is a wide range in oxygen needs among Protozoa. Obligate aerobes are limited to habitats with adequate oxygen concentrations; certain aerobes, however, grow best at oxygen tensions below that of the normal atmosphere.

Obligate anaerobes, on the other hand, are restricted to environments lacking oxygen—e.g., natural waters loaded with putrefying material, the lower levels of deep lakes, Imhoff sewage tanks, the intestines of vertebrates, etc.

Typical aerobes utilize the cytochrome system—a terminal oxidative system characteristic of aerobic organisms—in their major oxidative pathway. However, the genus *Trypanosoma* is interesting in that certain species are sensitive to cyanide poisoning, which blocks the cytochrome pathway, while others are rather insensitive. Such data suggest that some oxidative pathway other than the cytochrome route is important in the insensitive species.

5. Temperature and Other Relationships.—The biothermal range varies with the species and, in such cases as *Tetrahymena pyriformis*, with strains of species. Under laboratory conditions, the range for free-living Protozoa usually falls within the limits 7°–40° C (about 45°–104° F), and most species fail to grow above 35° C. In a few instances it has been possible to raise the upper limit by greatly increasing vitamin or amino acid allotments; for example, *Ochromonas malhamensis* can survive at 38° C when given about 3,000 times as much vitamin B₁₂ and about 1,000 times as much thiamine as it requires at 34° C.

In general, temperatures near 45° C (113° F) seem to be lethal for active stages, although certain heat-tolerant strains (thermophiles such as amoebas from hot springs of 53° C) are exceptions. Encysted stages of certain species may survive short exposure to temperatures somewhat higher than those lethal for active stages; in rare instances (e.g., *Colpoda*) dried cysts have remained viable for an hour or more at about 100° C (the boiling point for water, at sea level). At sublethal levels, high temperature has caused bleaching of *Euglena gracilis* in darkness. Low temperatures tend to be less harmful to Protozoa than high temperatures; for example, species of *Trypanosoma*, *Trichomonas*, and *Plasmodium* remain viable for weeks at temperatures of –20° to –70° C (–4° to –94° F).

Experiments with freshwater Protozoa have shown that tolerance to increasing salinities varies with the species and even with strains of a single species. In gradually adapted *Tetrahymena pyriformis*, for example, one strain grows well at a salinity higher than that of natural seawater, whereas another strain fails to survive at the salinity equivalent to 80% seawater. Although a few Protozoa (e.g., certain species of *Bodo*, *Colpoda*, *Uronema*) survive direct transfer to seawater, such an abrupt transfer is usually lethal. Stepwise transition to seawater is more easily tolerated; e.g., by species of *Amoeba*, *Cyclidium*, *Euglena*, *Euplotes*, *Lionotus*, *Paramecium*, *Phacus*, *Stylonychia*, and *Tetrahymena*. Several marine amoebas can also be shifted gradually from their normal habitat to fresh water without apparent damage. For such organisms no absolute physiological barrier separates marine and freshwater habitats.

Growth of Protozoa is generally restricted to a pH range from 3 (moderately acidic) to 9 (moderately basic). Certain species can survive for short periods outside this range, within the limits pH 2.5–11. Reported optimal conditions for protozoan growth in laboratory cultures range from about pH 4.5 to 7.5 or higher in different species.

6. Life Cycles.—A life cycle may often be considered a series of changes through which an organism passes in correlation with environmental changes. Completion of a cycle may seem to depend directly upon environmental change. Malarial parasites, for example, must have access to two kinds of hosts at particular periods in the life cycle. At the other extreme, environmental change is not essential for the cyclic changes in reproduction of Suctorida.

The complexity of protozoan life cycles varies considerably. The simplest involve an active trophic stage and an inactive cyst. Modifications include: (1) introduction of more than one trophic stage (dimorphism, polymorphism); (2) production of more than one kind of cyst; and (3) addition of a sexual phase. Life cycles of the simplest type are known in certain intestinal amoebas and flagellates, a few of which seem to have lost even the ability to encyst.

The simplest modification of the basic cycle involves trophic

dimorphism. Some of these dimorphic cycles show adult and larval stages, the latter being perhaps the more indicative of ancestral relationships. Other dimorphic cycles include amoeboid and flagellated stages, as seen in certain Mastigophora (e.g., *Tetramitus*) and Sarcodina (e.g., *Naegleria*). Flagellated and non-flagellated trophic stages occur in certain Mastigophora. In addition, amoeboid and plasmodial stages appear in certain Sarcodina (Mycetozoida, Vampyrellidae). More complicated cycles, with asexual and sexual phases, are known in various parasitic Protozoa; in such cases as malarial parasites the asexual phase occurs in one type of host (vertebrate) and the sexual phase in another (mosquito).

The ability to encyst is widespread in Protozoa, though not universal. Cysts vary in both structure and function. Some are primarily protective, enclosing a dedifferentiated (physically simple) "resting" stage. Reproductive cysts serve mainly as containers for reproductive stages and may have little protective value. Protective cysts may be produced by: (1) active stages, which undergo dedifferentiation before completion of the cyst; (2) zygotes, as in gregarines and phytomonad flagellates (e.g., *Volvox*); (3) gametocytes, as in Coccidia that encyst before syngamy; and (4) sporoblasts, division products of the zygote in many Coccidia.

The wall of a protective cyst is typically thick and often compounded of several layers, one is often thicker than the others and mainly responsible for protection. The wall may be mainly protein (ectocyst and mesocyst in many ciliates); keratin-like (certain parasitic amoebas and flagellates); mainly carbohydrate (endocyst of ciliates); mainly cellulose (certain dinoflagellates); siliceous material (chrysomonad flagellates); chitin (*Pelomyxa*); or foreign materials such as sand grains (certain foraminifers). Some cysts (e.g., *Colpoda cucullus*) are quite resistant to desiccation; thoroughly dried encysted *C. cucullus* remain viable for some time at temperatures of 80°–100° C.

Reproductive cysts, with thinner walls, are developed in certain Protozoa prior to fission, budding, or gametogenesis and syngamy. Certain gregarines, for example, pair and secrete a common cyst, within which gametogenesis and syngamy occur. Analogous behaviour is known for certain foraminifers.

Encystment often includes extensive preparatory changes in the organism: food vacuoles tend to disappear; precystic organisms often store food; flagella or cilia are usually resorbed; and the pellicle usually changes its consistency so that the body rounds up. A decrease in volume, perhaps partly from loss of water, is common. Encystment can be induced by various methods in the laboratory, even by vitamin deficiency in certain species, but the primary stimulus—if there is a single one—is still to be identified.

In excystment, the organism must regenerate the locomotor organelles of the trophic stage and escape from the cyst. Rupture of the membranes is effected in some species by absorption of water. Digestion of the endocyst has been reported in ciliates. Emergence through a pore, previously covered by a thin membrane, occurs in certain ciliates (e.g., *Bursaria*) and in some amoebas. Excystment can also be induced by a variety of laboratory methods, ranging, in various species, from immersion of cysts in distilled water to treatment with mixtures of salts, sugars, and vitamins.

7. Species Interaction.—A variety of relationships exist between protozoans and other organisms. On the basis of their relations with the host, dependent types are usually classified as commensals, symbionts, or parasites. A commensal receives food (in excess of the host's needs) and shelter but causes no apparent damage to the host. A symbiont receives the same benefits and also contributes something of value to the host; for example, certain flagellates of wood-eating termites benefit their hosts by digesting wood chips, which cannot be digested by the termites themselves. Likewise, certain intestinal ciliates of ruminants are known to produce cellulose-splitting enzymes not produced by the hosts; in addition, some of the ciliates may serve directly as food, passing from the rumen into the lower digestive tract. Protozoan parasites live on the surface (as ectoparasites) or inside the body (as endoparasites) of a host, another animal

or plant. Parasites that cause appreciable damage to their hosts are called pathogens. Although pathogens form a minority among parasitic Protozoa, some cause diseases of major importance.

Both free-living and parasitic Protozoa may have parasites of their own, the latter combinations representing hyperparasitism. The invaders are sometimes Protozoa—e.g., Dinoflagellida, Suctorida, amoebas, Microsporida. Other parasites of Protozoa include small algae, bacteria, and fungi. The algal partners of *Paramecium bursaria* and similar ciliates are probably symbionts, other dependents of Protozoa may be commensals or pathogens, and supposed bacteria in *Euplotes* have been considered possible symbionts.

In order to maintain themselves, parasitic Protozoa must reach new hosts at intervals. Transfer by vectors, or carriers (mosquito, flea, tick, fly, bug, leech, etc.), is a very important method of dispersal in which the parasite typically passes part of its life cycle in the vector. Malarial parasites complete several stages in the mosquito. Most species of *Trypanosoma* also pass part of the life cycle in a vector (fly, bug, or leech). Infected vectors may inoculate parasites while feeding on a host or, as in *Trypanosoma cruzi*, may void parasites from the hindgut onto the skin of a host where they may be rubbed into a wound. In so-called mechanical vectors the parasites do not undergo any cyclic development. Flies, for example, may ingest inactive cysts of intestinal amoebas and simply spread them over wide areas, still encysted. Parasites of the digestive tract are usually spread by contamination of food or drink; venereal infection (e.g., *Trichomonas vaginalis*), during coitus; certain parasites of aquatic hosts, by active migration of parasites from old to new hosts. In addition, parasites from a female host may reach a host of the next generation by passage through the placenta (malarial parasites) or by invasion of individual ova before the infected parent lays its eggs (*Babesia bigemina* in tick eggs).

JOHN J. LEE
HYPOTRICHOMONAS, A PARASITE OF
THE HUMAN DIGESTIVE TRACT

A wide variety of Protozoa may invade a single species of host. Man is a fairly good example. The human mouth is invaded by a flagellate (*Trichomonas tenax*) and an amoeba (*Entamoeba gingivalis*); the small intestine, by a flagellate (*Giardia lamblia*) and a coccidian (*Isoospora hominis*); the large intestine, by four flagellates (*Chilomastix mesnili*, *Pentatrichomonas hominis*, *Retortomonas intestinalis*, *Tricercomonas hominis*), five amoebas (*Dientamoeba fragilis*, *Endolimax nana*, *Entamoeba coli*, *E. histolytica*, *Entamoeba bütschlii*), and a ciliate (*Balantidium coli*); the urogenital tract, in both male and female, by *Trichomonas vaginalis*; the blood or other tissues, by six flagellates (*Leishmania donovani*, *L. brasiliensis*, *L. tropica*, *Trypanosoma cruzi*, *T. gambiense*, *T. rhodesiense*) and four malarial parasites (*Plasmodium falciparum*, *P. malariae*, *P. ovale*, *P. vivax*).

Some of the foregoing organisms are parasites, others probably commensals. The amoeba and flagellate of the mouth, though frequently associated with pyorrhea, are not proven causative agents of the condition. *Giardia lamblia*, although it does not invade the tissues, may be responsible for such disturbances as diarrhea and nausea. *Isoospora hominis* cannot complete its life cycle without destroying epithelial cells, and the self-perpetuating infection usually induces a fairly prolonged attack of diarrhea. The flagellates and the amoebas of the colon (except for *Entamoeba histolytica*) probably approach the status of commensals in most infections, although there may be concomitant digestive disturbances.

Entamoeba histolytica, on the other hand, usually actively invades the tissues, and is the proven causative agent of amoebiasis.

(see DYSENTERY: *Amoebic Dysentery*). *Balantidium coli*, which commonly invades the wall of the colon, causes symptoms similar to those of primary amoebiasis, but generally less severe. Invasions outside the digestive tract are unknown in balantidiasis. The malaras, caused by *Plasmodium* species, are always characterized by extensive destruction of red corpuscles, with resulting anemia and paroxysms of alternating fever and chills (see MALARIA). Leishmaniasis—visceral, dermal, and mucocutaneous—involves multiplication of certain *Leishmania* species in certain organs or in the skin (see LEISHMANIASIS). Trypanosomiasis in man is represented by African sleeping sickness and by Chagas' disease in the Western Hemisphere. Sleeping sickness (caused by *Trypanosoma gambiense* and *T. rhodesiense*, both transferred by tsetse flies) is characterized by fever and marked physical weakness. Chagas' disease is caused by *T. cruzi*, and possibly one or two closely related species (see TRYPANOSOMIASIS).

III. STRUCTURE AND FUNCTION

The form of Protozoa varies widely—continually changing in active amoeboid species, fairly constant in species with heavy pellicles and tests. The spherical form is common in floating types, whereas sessile species are often conical and radially symmetrical. Swimming types, usually elongate, often show a spiral torsion that tends to mask a tendency toward bilateral symmetry. Even in species that are not amoeboid form may change—e.g., during attainment of maturity; during transformation from one stage to another in dimorphic or polymorphic life cycles; and often following a change of environmental conditions. In species with a relatively constant form, shape may be maintained by secreted coverings (pellicle, theca, test, lorica) or by skeletons.

1. Covering and Skeleton.—The cortex, or outer cytoplasm, is bounded by a plasma membrane, which is covered by the pellicle, ranging from a thin elastic layer (as in *Amoeba proteus*) to a thick and relatively rigid covering (*Phacus*, *Euplotes*). Even in *Amoeba proteus* the pellicle is not a simple membrane; electron micrographs show delicate fibrils projecting outward to produce a hairy appearance. In *Euglena gracilis* the pellicle (apparently proteinaceous) shows alternating thick ridges and thin flexible strips, structure presumably favouring euglenoid movement (metaboly). The pellicle of *Peranema trichophorum* appears to be a double wall; that of certain gregarines contains three layers. Pores in the pellicle of ciliates and various euglenoids serve for the emergence of cilia, trichocysts, and various secretions.

A cellulose theca, which resembles the cell wall in higher plants, replaces the pellicle in many dinoflagellates (e.g., *Peridinium*) and phytomonad flagellates (e.g., *Chlamydomonas*). The theca may be impregnated with minerals like silica to form a rigid wall. In the armoured dinoflagellates the theca consists of plates, the number and arrangement of which serve as taxonomic criteria.

A secreted test, or "shell," composed mostly of inorganic material, often salts of silicon or calcium, may be present (as in *Arcella*, *Euglypha*, and many foraminifers). In arenaceous tests *Centropyxis*, *Diffugia*, and various foraminifers, sand grains, diatom shells, or similar materials may be cemented together.

Reproduction of testate rhizopods may be preceded by secretion and storage of plates, or collection and storage of sand grains to be used in construction of a new test by the daughter organisms. Foraminiferan tests often show several to many chambers produced in succession during growth of the organism.

The lorica, found in certain flagellates and ciliates, is a conical or sometimes tubular covering with an opening through which the anterior part of the body or its appendages may be extended. The wall either is secreted or is built of foreign particles. Lori-

cate species are sessile, floating, or free-swimming.

Radiolarian skeletons are composed either of silica or mainly of strontium sulfate. In the latter case the basic components are rods that pass through the centre of the organism. Siliceous skeletons, which show great variety, are often complex lattice-works, with one layer or two or more concentric layers.

2. Cytoplasm and Inclusions.—The jellylike colloidal cytoplasm surrounds the all-important nucleus and a number of other inclusions such as vacuoles, mitochondria, pigment bodies, food reserves, etc.

Nucleus.—Protozoa may have one or more nuclei at maturity, depending upon the species; some, in fact, contain hundreds of nuclei. In all Protozoa except the true ciliates and possibly certain foraminifers, multiple nuclei are apparently all alike at any given stage of the life cycle. In the ciliates, however, two types of nuclei, the micronucleus and macronucleus, differ in size, structure, and behaviour. One or more nuclei of each type may be present in different species. The micronucleus takes an active part in conjugation and autogamy, whereas the macronucleus appears to be involved mainly in the usual vegetative nuclear functions.

Nuclei of different species vary in such structural details as amount of chromatin, number and size of chromosomes, and presence or absence of an endosome, or nucleolus. Typical endosomes give negative Feulgen reactions, indicating the absence of chromatin. The endosome of *Euglenida* is an approximately central body that divides in mitosis; in parasitic amoebas, the endosome disappears early in mitosis.

The appearance of dark-staining chromatin matter in nondividing (interphase) nuclei usually suggests granules on a faintly stained network, an appearance probably produced by coils in the dispersed chromosomes. Electron micrographs indicate that the nuclear membrane is a double wall containing many pores. The macronucleus of ciliates contains many small chromatin granules and a variable number of endosomes. Deoxyribonucleic and ribonucleic acid are both present, the latter being much more abundant. Both form and number of macronuclei vary from species to species. Individual macronuclei are often compact spheroid bodies (as in *Paramecium*), but may be much elongated (as in *Vorticella* and *Euplotes*). The macronuclear apparatus of *Spirostomum* and *Stentor* is represented by a chain of "nodes" joined by filaments.

The significance of nuclear dimorphism in ciliates has remained a puzzle, particularly in view of the fact that both kinds of nuclei are derived from the single zygotic nucleus formed during conjugation. In certain ciliates differentiation of a new macronucleus involves repeated longitudinal splitting of chromosomes to produce polyploidy. Such behaviour is in agreement with the observation that in *Paramecium* the macronucleus contains about 40 times as much deoxyribonucleic acid as the micronucleus. Although usually supposed to be concerned primarily with sexual phenomena and thus essential for conjugation, the micronucleus is not required for fission in certain ciliates since strains lacking it are known in several species. For example, older strains of *Tetrahymena pyriformis*, maintained on artificial culture media, are all amiconucleate; other strains isolated in the laboratory have also lost the micronucleus. The apparent stability of amiconucleate *Tetrahymena* strains over periods of years indicates that the macronucleus has a definite genetic function, at least in these strains. Experiments with fragments have shown also that the macronucleus, or an adequate portion of it, is essential for regeneration, whereas the micronucleus ranges from indispensable (in certain hypotrichous ciliates) to nonessential (in typical heterotrichous ciliates).

Mitochondria vary from small ovoid or spherical bodies to rods or filaments in different species. Available evidence indicates that important respiratory enzymes are associated with protozoan mitochondria, just as with mitochondria of higher organisms. Other cytoplasmic inclusions include: the vacuome, small globules or vacuoles that can be stained with neutral red in the living organism; volutin granules; Golgi material, groups of flattened, closely packed vacuoles similar to the Golgi bodies reported in

JOHN J. LEE AND HUGO D. FREUDENTHAL
RADIOLARIAN SKELETON SHOWING
INTRICATE LATTICEWORK

metazoan cells; and crystals, typically enclosed in vacuoles and possibly representing metabolic wastes.

Vacuoles.—Contractile vacuoles are characteristic of freshwater Protozoa but occur also in certain parasitic ciliates and in many marine ciliates. Contractile vacuoles show cyclic expansion and contraction, the periodicity varying with the species, environmental conditions, and physiological activity. When expansion (diastole) is completed, the contents are discharged abruptly (systole) through a temporary or permanent pore. In many ciliates at least, position of the pore is constant enough to have taxonomic significance.

The major function of the contractile vacuole is elimination of excess water, which enters by osmosis (in freshwater species especially), accompanies ingested food, or accumulates metabolically. Vacuolar activity is influenced by changes in osmotic pressure and temperature and by phagocytic feeding. In some freshwater protozoans, vacuolar activity has been stopped completely by adding sugar to a freshwater medium (*i.e.*, increasing osmotic pressure). Although fluid eliminated by the contractile vacuole may contain some metabolic waste, available data indicate that this excretory function is of minor importance. Furthermore, many Protozoa have no contractile vacuoles.

Digestive vacuoles are typical of holozoic Protozoa. In amoebas, which ingest food at any point on the surface, the lining of the food vacuole is derived from the pellicle or from the plasma membrane. In organisms with a definite "mouth" (cytostome and cytopharynx), the vacuole develops as an outgrowth from the cytopharynx. In suctorian ciliates, food vacuoles are formed in similar fashion at the bases of tentacles. Ingested food may be accompanied by a significant amount of water in organisms ingesting bacteria or other small particles. Fresh food vacuoles in *Amoeba* are surrounded by a thick granular layer, but the granular material disappears during digestion. After ingestion of food, the vacuolar contents usually become slightly acidic, remain at that level for a time, then gradually shift toward the neutral point. Any undigested residues are eventually eliminated, often at a specific point (called cytopyge or cytoproct) in the cortex of organisms that have a highly differentiated body wall, or at any convenient spot in amoeboid organisms.

Certain ciliates (*e.g.*, *Loxodes*, *Blepharobrosthium*) contain one or more peripheral vacuoles in which float small granules (statoliths). On the basis of superficial similarity to certain structures in coelenterates, these vacuoles have been considered statocysts. Another type of vacuole, perhaps containing gas in some species, occurs in the peripheral cytoplasm of floating types, such as radiolarians, and apparently is involved in flotation.

Chromatophores.—Many phytoflagellates possess chromatophores containing chlorophyll and other pigments. In *Chlamydomonas* and related flagellates the chromatophore is often single, fairly large, and cup-shaped, partially surrounding the nucleus. In contrast, euglenoids often have a number of small peripheral chromatophores. In electron micrographs, chromatophores of phytoflagellates show a lamellar organization, opaque layers alternating with electron-transparent layers, the pigments supposedly being localized at the interfaces.

Chlorophyll is the predominant pigment in green flagellates. However, the green colour of chlorophyll may be masked by other pigments to produce greenish-yellow, red, brown, or sometimes bluish chromatophores. Certain of these accessory pigments may be important in absorption of light for photosynthesis. Both accessory pigments and types of chlorophyll may vary from order to order. For example, the euglenoids contain chlorophylls *a* and *b*; the dinoflagellates, chlorophylls *a* and *c*. Lutein, a carotene derivative, occurs in chrysomonads but not in dinoflagellates. Comparable taxonomic differences involve other pigments.

Certain strains of *Euglena* undergo bleaching when grown in darkness for some time or when exposed to high temperature (36° C). Bleaching also has been induced by treating certain strains of *E. gracilis* with streptomycin or the antihistamine drug pyribenzamine. These colourless strains may not regain the ability to produce chromatophores. Such experimental results suggest that the presence or absence of chlorophyll is not in it-

self a thoroughly reliable taxonomic criterion.

Pyrenoids, apparently homogenous bodies (even in electron micrographs), are often associated with chromatophores in certain orders of phytoflagellates but not in others. Even in orders characterized by pyrenoids, Euglenida for instance, species within a genus may lack them. The function of pyrenoids is uncertain, although they are often assumed to play a part in synthesis of polysaccharides. However, similar polysaccharides are synthesized and stored by related phytoflagellates that do not contain pyrenoids.

Cytoplasmic Pigments.—The cytoplasm of many phytoflagellates and certain other Protozoa contains various pigments (violet, blue, green, yellow, brown, pink, red). The peculiar pink pigment of *Blepharisma undulans* is bleached when the ciliates are exposed to weak light and is regenerated in darkness. In bright light this pigment or some product becomes toxic to *Blepharisma* and may cause lysis of various other Protozoa and small Metazoa. Red pigments and toxins are produced by some phytoflagellates—certain dinoflagellates (*Gonyaulax*). In blooms of dinoflagellates called "red tides," enough toxin may accumulate to cause death of large numbers of fish. A red pigment in *Euglena rubra* is shifted

toward the surface when this flagellate is exposed to high temperatures (35°–45° C) or to bright light.

Food Reserves.—Many Protozoa synthesize and store carbohydrates and lipids as food reserves. The type of stored carbohydrate varies with the group—*e.g.*, starches in Phytoomonadida, Dinoflagellida, Cryptomonadida; paramylum, another glucose polymer, in Euglenida; leucosin, believed to be a different

JOHN J. LEE AND HUGO D. FREUDENTHAL
GYMNODINIUM, ONE OF THE DINOFLAGELLATES RESPONSIBLE FOR THE POISONOUS "RED TIDES" OFF THE FLORIDA COAST

glucose polymer, in Chrysomonadida; and glycogens, in many other Protozoa. In phytoflagellates especially, these carbohydrates are commonly stored as discrete bodies, such as the paramylum bodies of Euglenida and starch bodies in Cryptomonadida. Glycogens, isolated from a flagellate, *Trichomonas*, and a ciliate, *Tetrahymena*, are chemically similar to, but not identical with, glycogen from mammals. Lipids are stored by many Protozoa, but the amounts apparently vary with the physiological condition of the organism. In pure cultures of flagellates and ciliates, lipids tend to accumulate as the culture grows older, suggesting a qualitative influence of the environment. Less is known about nitrogenous reserves, although chromatoid bodies of parasitic amoebas and volutin granules of many Protozoa may belong in this category. Volutin granules of certain trypanosomes and haemogregarines are destroyed by digestion with ribonuclease and have been presumed to contain ribonucleic acid.

Eyespots.—The light-sensitive stigma, common in chlorophyll-bearing flagellates, but rare in colourless ones, is believed to function in phototaxis, a behavioural response to light. In *Euglena* the stigma is a discoid mass of reddish granules near the wall of the canal that leads from the reservoir. At the level of the stigma, a small paraflagellar body on the flagellum is often considered the light-sensitive structure responsible for reaction to light. The stigma itself is believed to absorb the light that stimulates the paraflagellar body. In many flagellates with a stigma, however, there is no paraflagellar body. After experimental bleaching of *Euglena gracilis*, the stigma may disappear.

An analogous photoreceptor, the ocellus, has been described in certain dinoflagellates (*e.g.*, *Erythropsis*) as a mass of dark pigment partially enclosing a spherical hyaline body.

3. Locomotor Organelles.—These include pseudopodia, flagella, cilia, and certain structures derived from flagella and cilia. Cilia are the only organelles limited to a single group of Protozoa, the Ciliophora, or ciliates.

Pseudopodia.—These temporary protoplasmic extensions are of four main varieties—lobopodia, filopodia, myxopodia (reticulopodia or rhizopodia), and axopodia.

Lobopodia, represented typically in *Amoeba proteus*, are fairly broad extensions with rounded tips. Very small lobopodia may be clear; larger ones usually show a granular core. The outer layer (ectoplasm) appears denser than the inner cytoplasm (endoplasm).

Filopodia are typically slender clear pseudopodia, usually tapering to the tip. They sometimes branch or form simple connections.

Myxopodia are filamentous pseudopodia that branch and connect to form networks in which the outer cytoplasm is obviously more fluid than the inner cytoplasm (when such a core is present). In certain foraminifers the slender myxopodia seem to contain no endoplasm. A striking feature of the network is the flow of granules in individual pseudopodia—toward the organism on one side and away from it on the other. The direction of flow is reversible. The sticky myxopodial net is an efficient food trap. Local fusion of pseudopodia encloses the food. In certain foraminifers (e.g., *Elphidium*) digestion is usually completed outside the test; however, in some species, food may be drawn inside. The myxopodial net may also function in construction of the test during growth, in formation of cysts, and in locomotion.

Axopodia resemble myxopodia in that the outer cytoplasm is the more fluid, as indicated by flowing granules, but the extensions tend to radiate singly from the body without forming complex networks. In typical axopodia the inner cytoplasm forms an axial filament. These pseudopodia, like the myxopodia, are sticky food traps.

Amoeboid movement depends upon protoplasmic flow, and involves gel-sol reversals. In *Amoeba proteus* it usually involves formation of a main pseudopodium into which the rest of the amoeba flows (see CELL). In locomotion of testate rhizopods (*Arcella*, etc.) the tip of each pseudopodium sticks to some surface, and contraction of the pseudopodia supposedly pulls the body toward the point of attachment. It is difficult to explain the activity of slender myxopodia in certain foraminifers; protoplasmic flow in different directions is apparent on different sides of pseudopodia in which no endoplasm can be seen.

Flagella.—A flagellum consists of an outer sheath, circular or flattened in cross section, and a central axoneme. The electron microscope shows the typical axoneme to be a bundle of nine pairs of fibrils surrounding two central ones. The bases of the fibrils form the blepharoplast, which appears as a granule when viewed in the ordinary light microscope. The sheath apparently encloses a matrix in which the axoneme is embedded.

In certain Mastigophora, fibrils (mastigonemes) project laterally from the sheath. A flagellum usually extends anteriorly from an anterior blepharoplast. Exceptions include a trailing flagellum, which extends posteriorly from an anterior blepharoplast; a longitudinal flagellum (dinoflagellates), which extends posteriorly from a lateral blepharoplast; a transverse flagellum (dinoflagellates), normally lying in a spiral groove (girdle), which extends partly or completely around the body; and a flagellum forming the margin of the undulating membrane (*Trichomonas*, *Trypanosoma*). In free-living species there are usually one or two, less commonly three or four; in parasites there are one to many.

Flagellar locomotion involves different mechanisms in different flagellates. For example, the flagellum may trace a spiral from tip to base or from base to tip, or may show planar undulations extending from base to tip or from tip to base, depending upon the species. In some cases a flagellum pushes and in other cases pulls the organism forward. In *Euglena* and various related types, movement of the flagellum causes rotation of the organism on its major axis and gyration about the general path of locomotion. In effect, the body moves through the water somewhat like a screw in such cases.

Cilia.—Cilia are similar to flagella in finer structure but are shorter and usually more numerous. Cilia are usually distributed in meridional or somewhat spiral rows, the pattern being characteristic of the species and thus useful in taxonomy. The axoneme arises from an apparently self-reproducing basal granule, or kinetosome, more accurately a tubular structure representing the ends of outer axoneme fibrils. The basal granules of many species are arranged in a characteristic pattern, corresponding to distribution of ciliary organelles. Since the granules, in contrast

to the cilia, can be demonstrated clearly by silver impregnation, they are useful in identification and in tracing morphological changes during reproduction or in successive stages of a life cycle. In certain ciliates a fibril extends inward from each basal granule to join other fibrils from granules of the same row to form a bundle of filaments, a longitudinal or spiral basal fibril (kinetodesma). These basal fibrils make up a fibrillar system believed by some biologists to facilitate coordination of ciliary activities. This assumption is supported by observations on *Euplotes*, in which destruction of major fibrils eliminates locomotor coordination. In addition to, or sometimes instead of, simple cilia, many species have compound organelles formed by fusion of cilia in rows or in tufts. Membranes are composed of longitudinal rows; membranelles, of short transverse rows; cirri, of tufts.

Myonemes.—Myonemes are superficial contractile fibrils in certain ciliates, gregarines, and flagellates, and presumably are responsible for rapid changes in shape. An example of the action of myonemes is seen in the wavelike constrictions of *Euglena* during euglenoid movement. Analogous fibres occur as "stalk-muscles" in various ciliates (e.g., *Vorticella*).

4. Trichocysts.—These bodies, in the cortex of certain ciliates and flagellates, may be widely distributed over the organism or restricted to certain areas (tentacles, papillae, the area around the mouth). Several types occur in ciliates. Mucoid trichocysts are elongated inclusions that, under artificial stimulation, may be ejected as visible bodies. Apparently similar inclusions occur in such flagellates as euglenoids. Filamentous trichocysts, seen in *Paramecium* and other ciliates, are discharged as filaments composed of a cross-striated shaft and a tip. Toxicysts, in *Dileptus* and certain other carnivorous protozoans, tend to be localized around the mouth. Upon discharge each toxicyst expels a long nonstriated filament with a rodlike tip. These filaments, which paralyze or cause disintegration of other microorganisms, serve in capturing food and presumably in defense. The functional significance of other trichocysts is uncertain, although those of *Paramecium* apparently can be extruded for anchorage during feeding. Cnidocysts of certain dinoflagellates (e.g., *Polykrikos*), similar to nematocysts of coelenterates, develop in the cytoplasm from recognizable precursors; their function is unknown. Filamentous trichocysts, with cross-striated shafts, occur in the flagellate *Oxyrrhis*. The analogous trichocysts of *Chilomonas*, a cryptomonad flagellate, show longitudinal striations.

IV. REPRODUCTION AND DEVELOPMENT

1. Asexual Reproduction.—Protozoa may reproduce asexually, by binary fission, budding, plasmotomy, or schizogony.

Binary Fission.—Binary fission involves nuclear division, duplication of organelles and approximately equal division of the body. Blepharoplasts, basal granules, and, in certain species, such organelles as chromatophores apparently divide. Various other structures (e.g., parabasal bodies, and locomotor organelles in many ciliates) are usually resorbed so that each daughter organism must produce its own equipment. Some or most of the somatic cilia or cirri may be resorbed during fission. In hypotrichs, for example, new ventral cirri are commonly developed in both daughter organisms. In such cases, however, the basal granules giving rise to such structures seem to have genetic continuity.

Fission in ciliates usually involves extensive dedifferentiation of the parental body, followed by reorganization with two centres of differentiation. In typical transverse division of ciliates, the anterior end of the posterior daughter is differentiated in contact with the posterior end of the anterior daughter. However, *Halteria* and similar ciliates undergo a reversal of polarity in

FIG. 2.—ASEXUAL REPRODUCTION IN PROTOZOA

FROM C. VILLE, W. WALKER, JR., AND F. SMITH, "GENERAL ZOOLOGY," 1963; REPRODUCED BY PERMISSION OF W. B. SAUNDERS CO.

early fission so that the posterior ends of the daughters are in contact.

Development of the new buccal ("mouth") organelles may involve extensive reorganization. The anlage, or beginning, of new buccal ciliature is often recognizable early in fission. The buccal anlage of the posterior daughter in *Tetrahymena* arises by multiplication of basal granules at a particular level in a specific ciliary row. This morphogenetic specificity is inherited generation after generation. The parental buccal apparatus is retained by the anterior daughter in *Tetrahymena* and comparable ciliates. In various others (e.g., *Bursaria*) the buccal organelles are resorbed and each daughter develops a new set. Sometimes the buccal apparatus (*Paramecium*, *Vorticella*) is self-reproducing in the sense that the anlage of the new apparatus for one daughter arises as basal granules produced by division of granules in the parental apparatus.

HUGH SPENCER
SIMPLE FISSION IN A PARAMECIUM

Budding.—Budding involves normal nuclear division but unequal cytoplasmic division. This method, producing either external or internal buds, is characteristic of Suctorida. Internal budding, as in *Tokophrya*, involves formation of a "brood pouch" by invagination of the cortex, or outer layer, of the ciliate. The bud is pinched off inside the pouch and, after development of cilia, is expelled by contractions of the parental body.

Life cycles of Suctorida illustrate clearly the genetic continuity of the basal granules. The nonciliated adult possesses only basal granules. In budding, some of the parental granules migrate into the cortex of the young organism, assume a specific arrangement, and give rise to the cilia of the larval stage. Later on, during metamorphosis into the adult, the external portions of the cilia are resorbed, leaving only the basal granules.

Plasmodium and Schizogony.—Schizogony, characteristic of many Sporozoa, typically involves a series of nuclear divisions, followed by rapid production of uninucleate buds. In extreme

cases many daughter nuclei become located near the surface of the plasmodial stage before the buds are pinched off, often leaving a residual mass of cytoplasm. In plasmodium an organism with many nuclei divides into two or more daughters, each with several nuclei.

2. Nuclear Changes.—The chromosomes of Protozoa are frequently small and sometimes quite numerous; reported counts range from 2 to more than 1,600. The count of two, for growth stages of malarial parasites, probably represents a haploid (or half set) condition. The highest counts, which need verification, have been reported for certain

JOHN J. LEE AND HUGO D. FREUDENTHAL
A FORAMINIFER UNDERGOING SCHIZOGONY. A FORM OF ASEQUAL REPRODUCTION

radiolarians. The small size and large number of chromosomes make it impossible to follow chromosomal changes throughout mitosis in most Protozoa. In *Holomastigotoides tusitula*, however, certain strains have two large chromosomes about 50 microns long (the red blood cell in man is 7.5 microns across).

Each chromosome contains a tightly coiled thread, or chromonema, attached at one end to a centromere (a self-reproducing granule attached to a spindle fibre), and forms a series of loose major coils within the chromosomal matrix. In a late stage of cell division (telophase) each matrix disappears, releasing the chromonema. As a result, the major coils loosen and tend to disappear as the chromonemata become untwisted within the nucleus. At this point, the nucleus is in the so-called "resting," or inter-

phase, stage. Each centromere and chromonema next undergoes duplication, the minor coils of the chromonemata being reproduced exactly. The daughter chromonemata now unwind; each acquires a matrix, begins to contract, and develops a series of major coils as the next cycle of cell division begins with the appearance of a prophase chromosome.

Although it may be possible eventually to interpret mitotic behaviour of chromosomes in Protozoa, generally, in terms of the *Holomastigotoides* pattern, there are obvious differences among species in the relation of chromosomes to the spindle—a temporary cell structure closely associated with the movement of chromosomes during cell division. In some cases (e.g., typical micronucleus of ciliates, various flagellates, etc.) the spindle lies within the nuclear membrane. In many other cases the spindle is extranuclear, chromosomal fibrils being attached to centromeres at the nuclear membrane (e.g., *Holomastigotoides*, various other flagellates, and such Sporozoa as *Aggregata*). There is no conclusive evidence that the division of the ciliate macronucleus involves mitosis. Visible details vary with the genus or larger group of ciliates.

The onset of nuclear division in ciliates is correlated with changes in ciliature. In *Stentor coerulesus*, for example, macronuclear condensation normally begins just after a new field of basal granules, the buccal anlage, begins to differentiate. If this anlage is cut out as soon as it is detected, no macronuclear condensation occurs; if it is removed after condensation has begun, there is no further change in the macronucleus. Precocious fission has been induced by grafting a young *Stentor* to a mature specimen about ready to divide; apparently, a stimulus of undetermined nature is transmitted from the dividing ciliate to its immature parabiotic twin.

3. Sexual Phenomena.—The essential feature in sexual activities is the production of haploid gametic nuclei and their subsequent union to form a diploid zygote (zygotic nucleus). Reduction division (meiosis), to produce the haploid condition, occurs at different stages in different species. Zygotic meiosis, in phytomonad flagellates and at least certain gregarines and coccidians, ensures that all stages except the zygote are haploid. Gametic meiosis (during formation of gametes) has been described in certain Mastigophora, Sarcodina, and Sporozoa. Gametic meiosis of ciliates is often termed conjugant meiosis. On the basis of superficial features, several varieties of sexual phenomena are recognized: syngamy, autogamy, and conjugation.

Syngamy.—Syngamy, involving fusion of haploid gametes to form a zygote, is found in all major protozoan groups except ciliates. Within each subphylum, however, distribution of syngamy is apparently erratic. Two of the best-known examples of syngamy occur in *Volvox* and the malarial parasites, both of which illustrate anisogamy (gametes obviously different). Superficially apparent isogamy (identical gametes) is known in some species of *Chlamydomonas*, for example, but these gametes are actually two physiologically different kinds. In homothallic species one population derived from a common ancestor can produce both kinds of gametes; in heterothallic species, each strain produces one kind of gamete.

Autogamy.—This method involves meiosis and subsequent fusion of haploid nuclei within a single organism. The process occurs in a few flagellates (e.g., *Barbulanympha*, *Rhynchonympha*, *Urinympha*) parasitic in the wood-roach, and also occurs in certain ciliates. Among the ciliates, autogamy is known in *Paramecium* and in *Tetrahymena*. Autogamy can occur in unpaired ciliates occasionally in ciliates already paired for conjugation, or in encysted stages (as in *T. rostrata*).

Conjugation.—In conjugation, pairing may be preceded by mating reactions (clumping) of ciliates, as in *Paramecium*. Direct pairing, without such clumping, occurs in many other cases (e.g., *Tetrahymena*, *Euplotes*). The micronucleus in each conjugant typically undergoes three pregamic divisions, the second of which is usually reductional. If there are several micronuclei, one of more of them may undergo the pregamic divisions, the details varying with, and sometimes within, the species. After nuclear exchange, the migratory gametic nuclei fuse with the

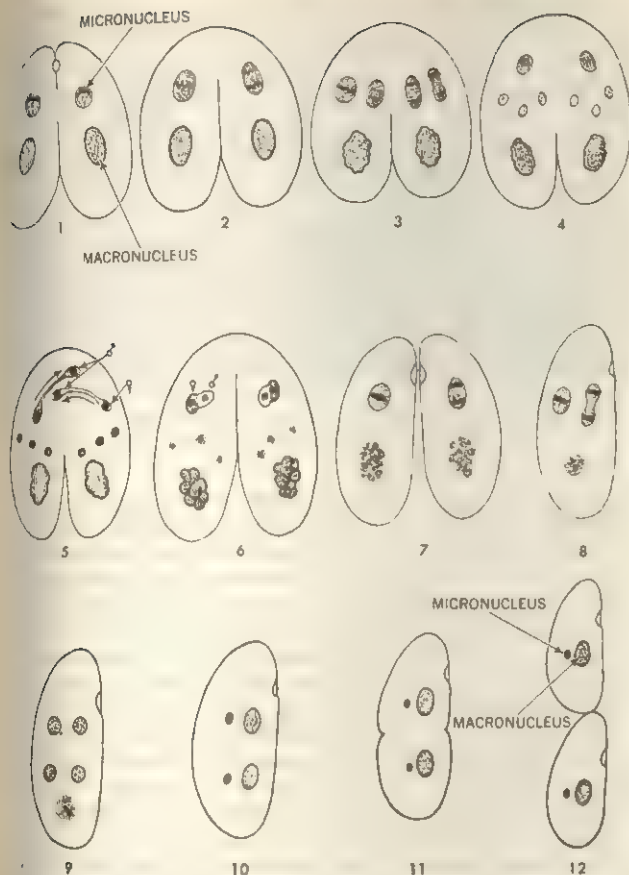

FIG. 3.—GENERAL PLAN OF CONJUGATION IN CILIATES

(1) The paired conjugants; (2) first pregametic division; (3) second pregametic division, reductional in most ciliates; (4) one haploid nucleus in each conjugant is dividing to produce migratory and stationary gametic nuclei; (5) exchange of migratory nuclei; (6) fusion of migratory and stationary gametic nuclei to produce a synkaryon in each conjugant; (7) each synkaryon divides as the conjugants separate; (8), (9) mitotic divisions producing daughter nuclei; (10) differentiation into macronuclei and micronuclei; (11), (12) fissions to restore normal nuclear number

stationary gametic nuclei to produce a synkaryon in each conjugant. In different species, one to four postconjugant nuclear divisions occur and the daughter nuclei differentiate into micronuclei and macronuclei. In production of the latter, there is a tremendous increase in the amount of chromatin. In certain ciliates this differentiation includes chromosomal division, and the mature macronucleus becomes polyploid. According to the number of nuclear divisions, reorganization fissions may be needed to restore the normal nuclear complement. Hence, a pair of conjugants may yield two to eight reorganized ciliates.

As prerequisites for conjugation, Maupas' factors (diverse ancestry, "sexual maturity," and starvation) still seem to be important, even for pure cultures of *Tetrahymena*. The maturity factor of Maupas seems to be expressed as the inability of appropriate strains to conjugate for some time after the preceding conjugation. This period of "immaturity" varies considerably—from none at all in certain strains of *Paramecium aurelia* to several weeks or months in some cases. Once suitable strains have reached "sexual maturity," conjugation can be induced readily by rapid starvation. This is effected with *Tetrahymena* by washing the ciliates and suspending them in distilled water. Maupasian "diverse ancestry" is illustrated by the presence of several mating types, or "sexes," in *Paramecium*, *Euplotes*, *Oxytricha*, and *Tetrahymena*. A particular species is composed of a number of varieties (syngens), each of which contains 2 or more mating types—e.g., 2 to 11 in *Tetrahymena pyriformis*; only 2 in *Paramecium aurelia* and *P. caudatum*. Normal conjugation occurs between members of different mating types within a single variety. The survivors, if any, of intervarietal matings usually show low

viability so that there may be reproductive isolation of these varieties within the species.

The survival value of sexual phenomena apparently varies with the species. In malarial parasites syngamy is an essential step that initiates the mosquito phase of the life cycle. In the free-living *Volvox* the zygote encysts to become a dormant resistant stage in which the flagellate can pass the winter. In ciliates, the survival value of conjugation is not so obvious. According to Maupas, strains of ciliates pass through a "cycle" of youth, maturity, and old age, leading to the death of the line. This fate can be prevented by conjugation during sexual maturity. In other words, conjugation rejuvenates the strain, an interpretation challenged by P. Enriques, L. L. Woodruff, and others, but supported by T. M. Sonneborn and his students.

4. Variation and Heredity.

—The genetic study of Protozoa involves the inheritance of detectable traits in fission or budding and the inheritance of such traits through syngamy or conjugation. Seemingly heritable changes sometimes occur in "asexual" strains. Examples include spontaneous changes in fission rate in clones of *Astasia* and the many instances of resistance to drugs developed in free-living and parasitic Protozoa. This resistance to drugs may be inherited over many divisions and over long periods of time after exposure to the inducing drug. The genetic status of such changes is uncertain, especially since syngamy is unknown in some of the species involved. Favourable material for genetic analysis is afforded by species that undergo syngamy or conjugation. In species showing syngamy, the dominant phase may be haploid or diploid, depending upon the type of organism. Ciliates, which undergo conjugation, are normally diploid, although experimentally induced haploid strains have been obtained in *Tetrahymena pyriformis*. Haploid species, such as typical phytomonad flagellates, offer obvious advantages to the geneticist. The heterozygous, or hybrid, condition exists only in the zygote so that hybrid analysis is much simpler than in ciliates. In these haploid cycles each division product of the zygote may give rise to a clone whose phenotype, or outward appearance, indicates the genotypic, or hereditary, constitution.

In investigations on the haploid *Chlamydomonas* and *Polytoma*, Mendelian inheritance has been reported for such traits as size, shape, rate of swimming (normal and "lazy"), photosynthesis (normal and slow), storage of volutin (normal and excessive), etc. Linkage has been established for certain pairs of traits, and crossing-over has been demonstrated in several cases.

Observations on traits inherited through conjugation range from size and fission rate to specific enzyme systems, some of the latter observations involving pure cultures of *Tetrahymena pyriformis*. For example, the wild strain of *T. pyriformis* is unable to synthesize serine and must have this amino acid in defined media. The ability to synthesize serine, known in certain mutant strains, seems to be inherited in Mendelian fashion as a recessive to normal (inability to synthesize serine). The status of the pyridoxine requirement in *T. pyriformis* is similar. Strains that grow without a source of pyridoxine, and synthesize it, appear to be homozygous recessives. When these are mated with the normal type (pyridoxine-requiring), all the progeny require pyridoxine. Mating types in *Paramecium*, *Tetrahymena*, and *Euplotes* also seem to be inherited in Mendelian fashion, although the genetic pattern may vary from one variety to another within a species.

There are indications that macronuclear differentiation during postconjugant fissions may influence determination of mating types in *Paramecium aurelia* (group A) and *Tetrahymena pyriformis* (variety 1). Inheritance of antigenic types in *P. aurelia* is apparently fundamentally Mendelian. The overall pattern shows some similarity to the inheritance of mating types, although antigenic types seem to be somewhat less stable under certain environmental conditions. Also dependent upon genetic

CONJUGATION OF PARAMECIA

composition of the ciliates are the abilities to maintain "infections" with kappa particles ("killer strains" of *P. aurelia*) and with mu particles ("mate-killer" strains of *P. aurelia*). *P. aurelia* that bear the killer trait contain cytoplasmic kappa particles, which secrete killer particles into the surrounding medium. All sensitive strains of paramecia die when they contact killer particles. Kappa particles seem to be self-reproducing but their persistence in individual ciliates is ultimately dependent upon a gene (or genes).

V. CLASSIFICATION AND SURVEY

The classification of Protozoa is not yet stabilized. A newer system, sponsored by the Society of Protozoologists, divides the phylum into five subphyla. The most obvious difference between the new system and the older one followed here is the separation of the Cnidosporidea from the rest of the Sporozoa as the subphylum Cnidospora. (Essentially similar treatment of the Sporozoa also was proposed about 40 years ago.) Less striking differences between the new system and the one followed here involve the taxonomic treatment of certain smaller groups.

A. MASTIGOPHORA

This subphylum consists of organisms flagellated in some stage of the life cycle. Formation of pseudopodia is not uncommon, and amoeboid stages occur in certain species.

1. Phytomastigophorea.—This class comprises the phytoflagellates, or plantlike flagellates, many of which have chromatophores containing chlorophyll. Species without chromatophores are morphologically similar to related chlorophyll-bearing species. Although the chromatophores contain chlorophyll, the colour varies with the kinds and concentrations of accessory pigments. Colourless species may be saprozoic or holozoic, and some of the chlorophyll-bearing forms also can ingest solid food.

Chrysomonadida.—Protozoans of this order may have one, two, or rarely three flagella, the third being a peculiar inactive organelle. Chromatophores, when present, are few, ranging from golden yellow to greenish yellow or brownish green. Holozoic feeding, by means of pseudopodia and without a permanent cytopharynx, is fairly common. Amoeboid and palmella stages occur in some species; occasionally either stage may be the dominant phase in the life cycle. Some colonial and solitary species secrete a lorica. Others secrete a membranous envelope in which siliceous scales or calcareous bits (coccoliths) are embedded. A specialized group of silicoflagellates is characterized by a siliceous skeleton. Stored reserves include leucosin and lipids. The cyst wall, typically siliceous, is formed inside the cytoplasm and has an emergence pore. A few genera develop spheroid or arboroid colonies. Genera include: *Ochromonas*, *Dinobryon*, *Synura*.

Heterochlorida.—This order of small flagellates is characterized by flexible bodies, two unequal flagella, and one to several yellow-green chromatophores. Leucosin and lipids are stored. The cyst wall is formed internally as in Chrysomonadida, but shows two valves and lacks a pore. A palmella or a plasmodium is the dominant phase in certain genera. Representatives are *Chloromonas* and *Nephrochloris*.

Cryptomonadida.—The members of this order have two flagella and often one or two chromatophores, rarely more, which may be blue green, brown, red, or occasionally green. The body is typically flattened on one side and convex on the other, and is fairly constant in shape. There is usually a ventral groove, which may be closed ventrally to form an interior pouch (*Cryptomonas*). In the colourless holozoic *Cyathomonas* the pouch has

(LEFT) DOUGLAS P. WILSON; (RIGHT) JOHN J. LEE AND HUGO D. FREUDENTHAL
TWO MEMBERS OF THE ORDER DINOFLAGELLIDA: (LEFT) LUMINESCENT NOCTILUCA SCINTILLANS; (RIGHT) A CELLULOSE-ENCASED CERATIUM

become a functional gullet. Starches and lipids are stored. Colourless types may be saprozoic (e.g., *Chilomonas*) or holozoic.

Dinoflagellida.—These are mostly marine flagellates of an order unique in the possession of a spiral groove (girdle, annulus) in which a transverse flagellum extends around the body. A longitudinal flagellum passes posteriorly in a longitudinal groove (sulcus) that extends anteriorly to the girdle or beyond. The theca is thin in unarmoured dinoflagellates, but in typical armoured types there is a heavy layer consisting of separate plates (e.g., *Ceratium*). Chromatophores may be brown, less commonly yellow, green, or blue green. Starch and lipids are stored. Holozoic feeding is common, not only in colourless types but at least occasionally in chlorophyll-bearing forms (e.g., *Gymnodinium*); ingestion by pseudopodial nets has been described in *Ceratium*. Under some conditions, dinoflagellates may become so numerous locally that the water is discoloured—e.g., the "red tides" well known in the Gulf of Mexico and elsewhere. Some dinoflagellates produce a potent toxin (e.g., *Gonyaulax*) that can kill fish. Such a toxin is sometimes accumulated in the tissues of mussels or other shellfish feeding on dinoflagellates. Consumption of these toxic shellfish may lead to occasionally fatal cases of poisoning in man. *Noctiluca* includes large specialized spheroid types up to two millimetres in diameter, widely distributed and responsible for much of the phosphorescence of agitated seawater. Certain dinoflagellates are parasitic in coelenterates and other animals.

Phytomonadida.—This is an order of fairly small (25 microns or less) flagellates, usually ovoid to spherical, but sometimes spindle-shaped or otherwise modified. The theca is usually a moderately firm envelope containing cellulose. The green chromatophore, when present, is usually single and cup-shaped, but two or more smaller chromatophores may be present. The chromatophore usually contains one or more pyrenoids. Some species are colourless saprozoic flagellates. Starch and lipids are stored. In addition, such types as *Haematococcus* may accumulate enough red cytoplasmic pigment to mask the green of the chromatophore; dense populations have been responsible for "red snow." A colonial series ranges from simple types such as *Gonium sociale*, with four zooids, to *Volvox*, species of which may contain 10,000–50,000 component flagellates. Syngamy is known for some species.

JOHN J. LEE
SYNURA, COLONIAL MARINE PROTOZOAN OF THE ORDER CHRYSOMONADIDA

JOHN J. LEE
MARINE EUGLENOIDS IN STAGES OF EUGLENOID MOVEMENT

Euglenida.—The members of this order are chlorophyll-bearing or colourless, with one to three flagella arising near the base of a flask-shaped reservoir (gullet) into which the contractile vacuole empties. The pellicle, if thin enough, permits metaboly, or euglenoid movement, but some genera (*Phacus*, *Menoidium*, etc.) have a rigid pellicle that prevents metaboly. A hard test (in *Trachelomonas*) or a lorica (in *Klebsiella*) may be present. Green chromatophores, when present, range from one to many, and may or may not be associated with pyrenoids. A stigma is characteristic of the green species, rarely of the colourless types. The major storage product is paramylum, a polysaccharide. Some colourless types (*Heteronema*, *Peranema*) are holozoic; others (*Astasia*, *Menoidium*, etc.) are saprozoic. Palmella stages may occur (e.g., *Euglena gracilis*), and cysts are known in several species.

Chloromonadida.—This order of the dorso-ventrally flattened freshwater flagellates is characterized by two flagella, one of them trailing. The numerous chromatophores are bright green. A stigma seems to be absent. Starch has not been reported. Glycogen and lipids are stored in certain species. Representatives are *Gonyostomum* and *Vacuolaria*.

2. Zoomastigophorea.

This is a class of saprozoic or holozoic flagellates, which lack chromatophores. They do not synthesize cellulose, starch, leucosin, or paramylum, although glycogen is stored by certain species. The flexible pellicle is thin enough in certain genera to permit considerable amoeboid activity. Many are parasites, the class being represented in presumably all vertebrates, many invertebrates, and certain plants.

Rhizomastigida.—This order contains organisms that have one to four flagella but also form pseudopodia (protoplasmic flow is sometimes more important than flagellar activity in locomotion). Representatives are: *Mastigamoeba*, uniflagellate, forming small lobopodia; *Histomonas* (*H. meleagridis* is associated with black-head disease in young turkeys and other birds); and *Mastigina*, uniflagellate, sluglike.

Protomastigida.—This is an order of small protozoans with one to two flagella and flexible pellicles but not typically amoeboid bodies. Many are holozoic, others saprozoic. Many parasitic species occur in vertebrates, invertebrates, and, occasionally, plants. Certain free-living species are colonial. In choanoflagellates a protoplasmic membrane can be extended to form a conical "collar" around the flagellum. Such flagellates (e.g., *Codonosiga*) resemble the choanocytes of sponges. Important parasitic species belong to the family Trypanosomidae, which includes *Trypanosoma*, parasites of vertebrates and invertebrate vectors; *Leishmania*, commonly represented in vertebrates and sand flies; *Leptomonas*, *Crithidia*, *Herpetomonas*, restricted to invertebrates; and *Phytomonas*, in certain plants and sap-sucking insects.

Polymastigida.—This heterogeneous order includes uninucleate, binucleate, and, rarely, multinucleate types. The majority are parasites. There are usually three to eight flagella, more in multinucleate species. Representatives are: *Costia*, parasites attacking the skin of fish; *Chilomastix*; *Giardia*; and several genera (*Dimenympha*, *Streblomastix*, *Pyrsonympha*, etc.) that include intestinal parasites of termites or wood-roaches.

Trichomonadida.—This order of uninucleate or multinucleate protozoans is characterized by three or more flagella, one or more parabasal bodies, and one or more axostyles. In multinucleate

types the many flagella occur in groups (mastigonts) associated with blepharoplasts, parabasal body, axostyle, and usually a nucleus; in a sense, they are compound flagellates. *Trichomonas* is represented in many vertebrate hosts; *Coronympha*, *Snyderella*, and *Stephanonympha* include multinucleate parasites of termites.

Hypermastigida.—The members of this order are uninucleate but multiflagellate parasites of cockroaches, wood-roaches, and termites. Many are holozoic, some ingesting particles of wood swallowed by their termite hosts. The flagella may emerge in anterior tufts, or in spiral or transverse rows covering part or sometimes most of the body. *Lophomonas* is represented in cockroaches; *Rhynchonympha*, in wood-roaches; *Holomastigotoides*, in termites; and *Trichonympha*, in both termites and wood-roaches.

Opalinida.—These opalinid ciliates, of disputed taxonomic position, are here given ordinal rank under the flagellates. The opalinids, never orthodox ciliates, may rest better among the Mastigophora, although their closest flagellate relatives are yet to be identified. These rather uniformly flagellated organisms divide obliquely or almost longitudinally, the plane of fission running parallel to the flagellar rows. Nuclei range from two (*Protoopalina*, *Zelleriella*) to many (*Cepedea*, *Opalina*). The bodies are flattened in *Zelleriella* and *Opalina*, rounded in the others. All are saprozoic parasites, most of them in the large intestine of amphibians, a few in snakes and fishes. The life cycles may be fairly complex, and syngamy occurs in the group.

B. SARCODINA

Except for species that develop flagellated stages, this subphylum contains protozoans whose locomotion involves protoplasmic flow, either with or without the formation of pseudopodia.

1. Actinopodea.—These organisms, forming a class, develop slender radiating pseudopodia, usually true axopodia. In some cases the slender pseudopodia apparently lack an axial core but otherwise resemble axopodia.

Helioflagellida.—The members of this order have one or more flagella in some stage of the life cycle and also develop radiating axopodia. In certain genera the axial cores of the pseudopodia converge in a central granule resembling that in certain uninucleate Heliozoidea. Representative genera are *Actinomonas*, *Ciliophrys*, and *Dimorpha*.

Heliozoidea.—This order consists of typically spherical, mostly freshwater organisms, floating or stalked, often with a test composed of separate scales or forming a continuous perforated wall. In nontestate genera there are many peripheral vacuoles. Heliozoidea usually feed on other microorganisms, occasionally on small Metazoa such as rotifers. Flagellated stages (gametes?) have been described in several genera, and syngamy also is known in a few species. Representatives are: *Actinophrys* (including the "sun animalcule," *A. sol*); *Actinosphaerium*, multinucleate types reaching a diameter of one millimetre; *Acanthocystis*, with a scaly test.

Radiolarida.—In this actinopodian order a central capsule separates the cytoplasm into intracapsular and extracapsular zones. The capsule, sometimes branched or lobed, rather than spherical or ovoid, is composed of chitin, pseudochitin, etc., and

(LEFT) ACANTHARIAN AND (RIGHT) RADIOLARIAN (GLASS MODEL), TWO MEMBERS OF THE CLASS ACTINOPODEA

may be somewhat flexible. The capsule encloses the nucleus, or nuclei. Most species have skeletons. In the Acantharia, or Actipylina, the basic skeletal elements, radially arranged spines containing strontium sulfate, pass through the capsule to converge centrally. These spines show a geometric constancy, polar, equatorial, and tropical spines being recognizable by analogy with the terrestrial sphere. Some species have secondary latticeworks or shells through which the spines pass. In other Radiolarida, skeletons are siliceous and quite varied in structure and complexity. Zooxanthellae, symbiotic dinoflagellates, in some cases live in the intracapsular cytoplasm of many Acantharia but are extracapsular in other Radiolarida. The zooxanthellae of some genera are dinoflagellates showing *Gymnodinium*-like active stages. Reproduction of simple Radiolarida involves fission, with division of the central capsule and distribution of skeletal elements. In other cases plasmotomy results in juvenile organisms that differentiate into the adult form during growth. Flagellated gametes and syngamy have been described. The extracapsular cytoplasm is often highly vacuolated, contributing to buoyancy of these floating organisms. Collapse of the vacuoles, increasing the specific gravity of the organisms and causing them to sink, apparently follows rough wave action. Radiolarida, typically pelagic, are widely distributed in the upper layers of all oceans. The skeletons sink to the bottom and become incorporated in sedimentary rock. Such radiolarian fossils have been recovered from Lower Silurian and later deposits.

2. Rhizopodea.—This class of Sarcodina is characterized by any kind of pseudopodia except axopodia. Many are equipped with tests (Testacida, Foraminiferida); others have only a thin pellicle.

Proteomyxida.—The majority of this order have filopodia or myxopodia, but *Labyrinthula* moves in a gliding manner without obvious pseudopodia or protoplasmic flow. Some *Proteomyxida* invade algae and Volvocidae; others may be found in eelgrass and hops. Little is known about their life cycles, but the mature stage is a plasmodium in some cases, a uninucleate amoeba in others. *Labyrinthula*, *Pseudospora*, *Vampyrella*, and *Leptomyxa* are representative.

Mycetozoida (Mycetozoa).—The slime molds are often considered fungi. The order includes the Acrasina, in which a pseudoplasmodium is developed. *Dictyostelium discoideum* has an unusual life cycle in which uninucleate amoebas form an aggregate (pseudoplasmodium) after responding to a chemical stimulus (acrasin, secreted by certain individuals). In the more typical group, the Myxomycetes, the mature stage is a plasmodium that, in extreme cases, may grow to a length of a foot or more. Representative genera are *Physarum*, *Physarella*, *Fuligo*, and *Ceratiomyxa*. *Plasmodiophora* and its allies invade roots and underground stems of higher plants and lead to the development of galls. (See SLIME MOLDS.)

Amoebida.—The members of this rhizopodan order have no test. Movement may involve pseudopodia or merely protoplasmic waves. There are one to many nuclei. Some of the Amoebida are small (e.g., four microns for small specimens of *Dientamoeba*); others, such as *Chaos (Pelomyxa) carolinensis*, may reach a length of four to five millimetres. In one family (*Dimastigamoebidae*) there are flagellated and amoeboid stages (*Dimastigamoeba*, *Naegleria*), but this dimorphism is unknown in other families. Other Amoebida include free-living species in fresh and salt water and parasites of many vertebrates and invertebrates.

Testacida.—This order of freshwater rhizopods is characterized by one-chambered tests. These protozoans creep by using pseudopodia that are either filopodia or very slender lobopodia. In a few genera (e.g., *Pamphagus*) the filopodia tend to branch, resembling a very simple myxopodial net. The test is usually

two-layered, the inner one being a chitinous membrane sometimes strengthened with inorganic material. The outer layer may consist of secreted siliceous scales (*Euglypha*, etc.) or of foreign particles such as sand grains (*Diffugia*, etc.) embedded in a "chitinous" cement.

Foraminiferida.—The rhizopods of this order have myxopodia (reticulopodia). The tests, typically covered with cytoplasm, are generally much larger than those of Testacida, often reaching lengths or diameters of 2–5 mm., rarely 40–50 mm. Some of the fossil types (e.g., *Camerina*) exceeded 100 mm. The wall of arenaceous tests contains sand grains, fragments of tests from other animals, and similar foreign material held together by a secreted cement (siliceous, calcareous, or chitinous in different cases).

Secreted tests are composed of calcareous or siliceous materials similar to the cements of arenaceous tests. In many species the test contains pores through which the cytoplasm extends, and usually has an aperture at one end. In more primitive types (*Microgromia*, *Diplogromia*, etc.) the test has a single chamber. In others there are several to many chambers constructed in series during a growth period of several weeks to six months or longer in different species. The pattern in which the chambers are arranged is an important taxonomic characteristic. Foraminiferida are rarely pelagic, mostly bottom-dwelling animals whose tests, through geological ages, have become incorporated in sedimentary rock, especially limestones, with particular types appearing in specific deposits. For this reason, foraminiferan fossils are useful for identifying strata, especially in drilling for oil. *Globigerina* ooze, formed at certain ocean depths, represents recent deposits containing tests of *Globigerina* and related foraminifers. See FORAMINIFERA.

GLOBIGERINA, A RHIZOPOD OF THE
ORDER FORAMINIFERIDA

C. SPOROZOA

As often defined, the subphylum Sporozoa includes several groups of parasites not very closely related. Although their name implies that spores are produced, this is true for only some of the Sporozoa. Saprozoic feeding apparently is predominant; however, phagocytic activity is known in malarial parasites and *Nosema*, among others. The subphylum is usually subdivided partly on the basis of structure of spores and timing of sporulation: Telosporidea, sporulation following syngamy; Cnidosporidea, spores with polar filaments, sporulation before syngamy; Acridosporidea, a probably heterogeneous group producing spores without polar filaments.

1. Telosporidea.—In this class there is typically an alternation of asexual and sexual phases, the latter producing infective stages (sporozoites) in which the parasites are usually transferred to new hosts. Sporozoites initiate the asexual phase, in which the parasites (except for most gregarines) undergo merogony. Sooner or later gametocytes are produced; then gametogenesis and syngamy occur. The zygotes undergo another schizogony (sporogony) which yields sporozoites. In such Telosporidea as malarial parasites, gametocytes are transferred to an invertebrate host (mosquito or other vector) for the sexual phase of the cycle. In other cases (e.g., typical coccidians) both sexual and asexual phases occur in one host.

Gregarinida.—These sporozoans constitute a subclass of Telosporidea. They are mostly parasites of invertebrates, especially annelids and arthropods, although a few occur in tunicates and hemichordates. Gregarines may be found in such cavities as the digestive tract, seminal vesicles (annelids), Malpighian tubules (certain insects), gonads (mollusks), and the coelom (annelids, echinoderms). The mature gregarine, which may measure two to ten millimetres in extreme cases, is typically elongated, ovoid

ROMAN VISHNIAC
FRUITING BODIES OF PHYSARELLA
OBLONGA, ORDER MYCETOZOIDA

to spindle-shaped, either flattened or more or less circular in cross section. There is usually a well-developed pellicle. The cortical cytoplasm may be differentiated into two layers, the deeper layer containing myonemes. In certain species both longitudinal and circular myonemes are responsible for changes in shape of the body. In the cephaline gregarines, anterior and posterior portions of the body are marked off by a transverse membrane, a structure lacking in acephaline gregarines. In certain cephaline species the anterior segment bears a structure that anchors the parasite to some tissue of the host during the growth phase. Although saprozoic nutrition is predominant, ingestion of tissue cells has been reported (e.g., in *Monocystis*, *Aplocystis*). Life cycles resemble those of other Telosporidea except that gametocytes (gamonts) of gregarines encyst in pairs. Within this thin-walled gametocyst, oogenesis and syngamy occur. Each zygote secretes an oocyst and divides into sporozoites. The result is a spore, ready for transfer to a new host, in which sporozoites emerge from the cyst. Development of the sporozoite, in many species, begins inside a tissue cell but is completed in some body cavity (digestive tract, coelom, etc.). In the Schizogregarinida (*Schizocystis*, *Ophryocystis*, *Selenidium*, etc.) the mature trophozoite undergoes merogony. Each resulting merozoite may repeat the cycle of growth and merogony until, sooner or later, gametocytes develop to start another sexual phase. In Eugregarinida (*Gregarina*, *Monocystis*, *Diplocystis*, etc.) there is no merogony; each sporozoite reaching a new host grows directly into a mature gregarine. With certain exceptions (e.g., *Nematopsis* and *Porospora*, which have two different hosts, a mollusk and a crab or lobster) gregarines complete their life cycles within a single host.

Coccidia.—This subclass of Telosporidea includes parasites of vertebrates and invertebrates. They are primarily intracellular, mostly in epithelial tissues. Merogony occurs in the asexual phase and sporogony in the sexual phase. In certain genera (*Adeia*, etc.) gametocytes associate in pairs but do not produce a gametocyst. In other Coccidia (*Eimeria*, *Isospora*, etc.) the two kinds of gametocytes differentiate independently. Life cycles are usually completed within a single host. However, a two-host cycle occurs in certain genera (*Haemogregarina*, *Hepatozoon*, *Karyolysus*), the sexual phase involving an invertebrate host (beech, tick, mite, tsetse fly, etc.). Certain Coccidia are important as parasites of cattle, sheep, poultry, fox, mink, etc. *Isospora hominis* occurs in man.

Haemosporidia.—In this telosporidean subclass the zygote is extracellular for a time before sporogony begins. No true spores are developed. The sexual phase occurs in an invertebrate host that inoculates naked sporozoites into a vertebrate. In Plasmodium (*Plasmodium*) and Haemoproteidae (*Haemoproteus*, *Leucocytozoon*; development of sporozoites occurs in endothelial or related cells of the vertebrate. After exoerythrocytic merogony (one or more cycles) in *Plasmodium*, which includes the agents of malaria, some of the merozoites may invade erythrocytes to initiate a series of erythrocytic reproductive cycles. Others continue the exoerythrocytic cycle. Sooner or later, some of the erythrocytic merozoites become gametocytes, ready for ingestion by a mosquito, in which gametogenesis, syngamy, and sporogony occur. In *Haemoproteus* the stages that appear in circulating erythrocytes are gametocytes; gametogenesis, syngamy, and sporogony occur in bloodsucking flies (e.g., *Simulium*).

Babesia, *Theileria*, and related forms, often assigned to the Haemosporidia, show certain differences from typical examples.

JOHN J. LEE
GREGARINA, A SPOROZOAN PARASITE OF THE DIGESTIVE TRACT OF ARTHROPODS

However, vertebrate and invertebrate hosts are required, asexual stages of *Babesia* appear in red corpuscles, and a sexual phase occurs in the invertebrate. Although there may be schizogony in the invertebrate host in some cases, the reproductive stages described for *Babesia*, in the vertebrate, suggest fission rather than merogony. *Babesia* and related types are of some importance as parasites of cattle, sheep, goats, horses, and dogs. *Babesia bigemina*, the agent of Texas cattle fever, is of historical interest as the first protozoon shown to be transmitted by a vector (a tick). In their work on *Babesia* in 1893, Theobald Smith and F. L. Kilbourne thus paved the way for later discoveries demonstrating the widespread importance of vectors in the transfer of animal parasites.

2. Cnidosporidea.—This class is characterized by spores that differ from those of Telosporidea in the presence of one to four coiled polar filaments. The spore, its membrane often consisting of two or three valves, contains an infective stage (sporoplasm) analogous to a telosporidian sporozoite. The spore has a "multicellular" origin, in contrast to the spore of Telosporidea. The cells that produce the polar filaments and the spore capsule, and then degenerate, may be considered "somatic" cells with specific functions. The sporoplasm in *Nosema*, according to one account, is attached to a polar filament that, during extrusion from the spore, pulls the sporoplasm with it. Other observations indicate that the polar filament is a hollow tube through which the sporoplasm travels from the spore to a tissue cell of the host. The liberated sporoplasm eventually grows into a plasmodium.

Myxosporida.—This cnidosporidian order features bivalved spores containing one to four polar filaments and one sporoplasm. Most species are parasites of fishes, although a few invade reptiles and amphibians. Infections may involve body cavities (gall bladder, urinary bladder, kidney tubules) or various tissues, according to the species. Heavy infections are frequently fatal. Representative types are *Unicapsula muscularis*, causing "wormy disease" of the muscles in halibut, and *Myxobolus pfeiferi*, causing "boil disease" of barbel.

Actinomyxida.—In this order the spore has three valves, which are sometimes drawn out into spines. There are usually three polar filaments and one to many sporoplasms. Species are known from the coelom and digestive tract of annelids and sipunculids. *Sphaeractinomyxon* and *Triactinomyxon* are representative.

Microsporida.—This is an order of small, usually intracellular parasites that produce small (2–20 microns) spores with membranes not showing distinct valves. There are usually one sporoplasm and one polar filament, rarely two (*Telomyxa*). Microsporida occur in Myxosporida, flukes, tapeworms, nematodes, frogs, fishes, and arthropods. *Nosema bombycis* causes "pebrine" of silkworms, a disease investigated by Louis Pasteur in 1865. A related species, *N. apis*, was found to cause a serious disease of bees.

3. Acnidosporidea.—This is a heterogeneous class in which spores, if any, lack polar filaments. Organisms often included in the class fall into two distinct groups that may be designated as subclasses.

Sarcosporidia.—In this subclass mature stages (cysts) occur in striated or cardiac muscle in reptiles, birds, and mammals (horse, cattle, sheep, pig, etc.). All these parasites apparently belong to one genus, *Sarcocystis*. Infection leads to the appearance in muscle of characteristic sarcocysts containing many uninucleate "spores," which are not encysted and may be motile. Heavy infections may cause muscular weakness and emaciation.

JOHN J. LEE
PLASMODIUM IN HUMAN RED BLOOD CELLS: RING STAGE IN UPPER CELL, MEROZOITES IN CENTRE CELL

Production of an endotoxin (sarcocystine), quite toxic for rabbits, has been reported. Infections have been produced experimentally by feeding infected muscle to mice. The life cycle is incompletely known.

Haplosporidia.—This is a subclass in which the infective stage is an amoeboid form transmitted in a cyst (spore) that lacks polar filaments. The spore membrane may be bivalved, operculate, or drawn out into tails or filaments. Species occur in copepods and other crustaceans, insects, lower chordates, fishes, annelids, nemertines, tapeworms, and certain protozoans. Haplosporidia may live in body cavities or may invade epithelia. The trophozoite, upon liberation from the spore, typically develops into a plasmodium. In certain species uninucleate sporoblasts become differentiated within the plasmodium and produce spores. *Haplosporidium*, represented in annelids, tunicates, mollusks, and crustaceans, is the type genus.

D. CILIOPHORA

This protozoan subphylum contains only one class, Ciliata, organisms that differ from those of other groups in the possession of cilia or derivative organelles at some stage in the life cycle, in the presence normally of both macronuclei and micronuclei, and in the absence of true syngamy. Two subclasses constitute the class: Holotricha and Spirotricha.

1. Holotricha.—These ciliates lack cirri and the prominent membranelles characteristic of the Spirotricha. Many are uniformly ciliated, but the more specialized show extensive losses of cilia.

Gymnostomatida.—This is a large order in which the ciliation is commonly uniform except in certain genera where enlarged cilia surround the cytostome. There is no well-developed buccal cavity or vestibulum; the apical, anteroventral, or occasionally lateral cytostome opens usually at the surface of the body. The cytopharynx may be surrounded by rodlike trichites (as in *Prorodon*) or by a pharyngeal "basket" in which the skeletal elements are fused together (*Chilodonella*, etc.). The majority, equipped with trichites, are carnivores that can ingest large prey such as other ciliates. Those having a pharyngeal basket are herbivores.

Suctorida.—Members of this order are marine or freshwater forms, sessile or floating, without cilia in adult stages although the basal granules persist. Free-living adults have hollow suctorian tentacles for capture of prey and ingestion of food, which flows down a tentacle and into a food vacuole formed at its base. Reproduction involves budding; in most cases the bud is a ciliated larva that is active only a short period before metamorphosis. The adult stage may change directly into a ciliated stage, which later may turn into a suctorian form or may encyst. Many sessile Suctorida have stalks similar to those of various Peritrichida. *Endosphaera* includes parasites of certain Peritrichida; *Allantosoma* has been reported from the intestine of horses; *Podophrya*, *Tokophrya*, and *Acineta* include free-living types.

Chonotrichida.—Except for a few species of *Spirochona*, the members of this order are marine, and mostly sessile on swimming crustaceans. The adults are somewhat vase-shaped, the free end of the body being modified into a single or double funnel at the base of which lies the cytostome. This funnel has been considered analogous to the vestibulum of various other ciliates. Cilia of the adult stage may be reduced to those on the funnel. Reproduction involves budding; the ciliated larva resembles many Gymnostomatida. *Chilodochona*, *Stylochona*, and *Spirochona* are representative.

Trichostomatida.—These ciliates usually have a well-developed vestibulum leading to a ventral cytostome, but do not have a true buccal cavity. *Balantidium*, formerly considered a heterotrich, is included here. Some of the parasitic types (*Blepharocorys*, *Charon*, *Cyathodinium*) show a reduced somatic ciliation. Reproduction may occur in active stages or within a reproductive cyst by fission (Colpodidae) or budding (*Conidiophrys*). A ciliated larva appears in *Conidiophrys*, sessile ectoparasites of crustaceans.

Hymenostomatida.—The ciliates of this order have a buccal

cavity equipped typically (e.g., *Tetrahymena*) with a membrane on the right and a zone of membranelles on the left. In *Paramecium* occur peniculi, bandlike zones of cilia probably homologous with membranelles of other hymenostomes, and a small endoral membrane at the right margin of the buccal cavity, which probably corresponds to the membrane of other genera. Although hypertrophied membranes (e.g., *Pleuronema*) or membranelles (e.g., *Lembadion*) occur in certain genera, these buccal organelles are usually inconspicuous.

Astomatida.—This parasitic order shows no cytostome. The group may be phylogenetically heterogeneous. Most species are uniformly ciliated. Some have spinelike holdfast organelles, others (e.g., *Protoradiophrya*) contain skeletal fibrils of unknown function, and a few (e.g., *Haptophrya*) have an anterior sucker for attachment. Reproduction involves typical binary fission or, in certain genera, repeated fission without prompt separation, producing chains of individuals. Most species occur in annelids; a few in flatworms, crustaceans, and amphibians.

Apostomatida.—This is an order of specialized parasites, mostly in crustaceans, rarely in annelids. Except for such cases as *Cryptocaryum*, there is a small ventral cytostome surrounded by a peculiar rosette containing cilia. The homologies of the rosette which presumably functions in ingestion, are uncertain. A polymorphic life cycle, including fission in a cyst to produce migratory larvae, is known for several species. *Foettingeria* and *Gymnodinioides* are representative.

Thigmotrichida.—An anterior group of thigmotactic cilia is responsible for the name of this order, although such cilia, serving to attach these parasites to their hosts, are not restricted to Thigmotrichida. The cytostome and buccal ciliation lie in the posterior half of the body, and may even be terminal. A few genera (e.g., *Hypocoma*) have replaced the cytostome with a suctorial tentacle, apparently used for ingestion but perhaps not homologous with suctorian tentacles.

Peritrichida.—This large order contains mostly sessile, more or less conical ciliates, usually with a stalk, the matrix of which is secreted by a scopula, a differentiated area of cytoplasm at the pole opposite the cytostome. In Vorticellidae, the stalk contains a spiral muscle that can coil up, drawing the body down toward the point of attachment. Ciliation of the adult is usually limited to the oral disc—two or three semimembranes (component cilia fused basally) winding counterclockwise toward the cytostome. The outer organelle, becoming a membrane in the buccal cavity (infundibulum), is probably homologous with the buccal membrane of other ciliates. Fission, in sessile species, produces a sessile

daughter and a telotroch. The latter develops a ciliary girdle before completion of fission and swims for a time before undergoing metamorphosis, during which the locomotor cilia are resorbed. An adult also may develop a ciliary girdle, discard its stalk, and become a telotroch. Peritrichida include solitary (*Vorticella*) or colonial (*Carchesium*, *Epistylis*, *Zoothamnium*) stalked forms; more or less flattened ectoparasites and endoparasites (*Trichodina*, *Urceolaria*); loricate sessile types (*Coturnia*, *Vaginicola*); swimmers with rudimentary stalks (*Hastatella*); and permanent telotrochs (*Telotrichidium*).

PHILIP FEINBERG, FELLOW OF THE NEW YORK MICROSCOPICAL SOCIETY

VORTICELLA, A CILIATE WITH A LONG CONTRACTILE STALK

2. Spirotricha.—This subclass is characterized by prominent membranelles extending clockwise toward the cytostome. A buccal membrane may be present. Somatic cilia are often reduced in number and are replaced by cirri in Hypotrichida.

Heterotrichida.—This is an order in which ciliation is commonly uniform, with a tendency toward arrangement in longitudinal rows. Membranelles near the cytostome are well developed.

and, in certain genera, a buccal membrane lies at the right of the peristome. Many heterotrichs are large, some reaching a length of two millimetres. *Bursaria*, *Condylostoma*, *Spirostomum*, and *Stentor* are representative.

Oligotrichida.—Cilia are greatly reduced in number in members of this order. A series of membranelles is usually found near the cytostome and a spiral band of larger membranelles occurs anteriorly. An equatorial band of coarse cilia, or bristles, arranged in groups, may also be present. *Halteria* and *Strombilidium* are representative.

Tintinnida.—Mostly pelagic, loricate marine ciliates constitute this order. The more or less conical body is elongated. The zone of membranelles winds down the funnellike peristome, while cilia are sometimes limited to the anterior third of the body. The lorica, mainly organic material to which foreign particles are sometimes added, is an open tube in some species but is more often vase-shaped, closed at the pole opposite the cytostome. *Tintinnus* and *Tintinnopsis* are representative.

Entodiniomorphida.—In this order the ciliature may be reduced to small organelles variously located. These are the rumen ciliates of ruminants and similar ciliates of other herbivores (e.g., horses, elephants). In certain species the internal organization simulates a digestive tract. Certain species digest cellulose. *Diplodinium*, *Entodinium*, and *Cycloposthium* are representative.

Odontostomatida (= Ctenostomatida).—This order comprises small wedge-shaped ciliates with the mouth located on the base of the wedge. The oral (ventral) surface is flat or slightly convex; the dorsal edge approximates a semicircle or smaller arc. The pellicle is differentiated into longitudinal plates. Cilia are reduced to a few incomplete rows, and there are only eight to nine membranelles in the pouchlike buccal cavity. Most are freshwater types that thrive in putrefying material. *Discomorpha* and *Saprodinium* are representative.

Hypotrichida.—Members of this order are dorsoventrally flattened, with a firm pellicle, and with cirri usually limited to the ventral surface. Sensory bristles, perhaps rudimentary cilia, may occur in dorsal rows, less commonly on the ventral surface, adjacent to cirri. The large peristome is triangular and often shows a membrane at the right margin. The zone of membranelles may extend across the anteroventral or anterodorsal surface. *Euplotes*, *Oxytricha*, *Uronychia*, and *Gastrostyla* are representative of this order.

PROTURA, an order of minute (0.5–1.5 mm. long), pale, wingless, blind insects that live in damp humus and soil and feed on decaying organic matter. The order, which includes about 150 species and is worldwide in distribution, was unknown until 1907. Unlike other insects, proturans lack antennae and possess 12 complete abdominal segments, 3 of which are added postembryonically, one at a time, with nymphal molts. The front legs serve a sensory function, and are carried like antennae. The cone-shaped head carries the suctorial, stylelike mouthparts, largely retracted into it. The abdominal segments 1 to 3 have ventral processes called styli. Some au-

thorities do not regard Protura as true insects. See **APTERTYGOTA**; **INSECT**.

PROUD, JOSEPH (1745–1826), Swedenborgian minister and hymn writer with considerable gifts as a preacher, was born at Beaconsfield, Buckinghamshire, Eng., on March 22, 1745. The son of a General Baptist minister, he served Baptist churches at Kington, Fleet, and Norwich before in 1788 openly adopting the views of Emanuel Swedenborg. As a minister of the (Swedenborgian) New Church he gathered large congregations in Birmingham, Manchester, and London. His first volume of 300 hymns appeared in 1790 and was several times reprinted. A small book of hymns for children was published in 1810. Many of his compositions are of decided merit and continue to be used in Swedenborgian worship. Proud died at Handsworth on Aug. 3, 1826.

(E. A. PA.)

PROUDHON, PIERRE JOSEPH (1809–1865), French moralist and advocate of social reform, was born on Jan. 15, 1809, at Besançon, in the traditionally rebellious Jura mountain district of France. He came of a poor family and at 19 became a working compositor; later, as a proofreader, he acquired knowl-

ARCHIV FÜR KUNST UND GESCHICHTE, BERLIN
PIERRE PROUDHON, ENGRAVING BY
NORDHEIM, AFTER BAZIN

edge of theology, Latin, Greek, and Hebrew. Although he later won academic scholarships, he spurned formal training and remained a self-educated man. His interests turning to economics and politics, he published, in 1840, *Qu'est-ce que la propriété?* His answer, "Property is theft," does not, however, mark him as a socialist. Proudhon voices, instead, the typical middle-class objection to concentrated economic power and the consequent difficulty that small businessmen have long experienced in raising capital even when the security offered was perfectly sound. Far from demanding the abolition of private property in means of production, Proudhon urged that productive property be widely dispersed among owner-produc-

ers who would operate as individuals or band together in mutual benefit associations. Proudhon argued that the government should preserve an open door for investment in small businesses locally or mutually owned. To this end the government should establish a semipublic exchange and capital bank to take the place of the Bank of France and the stock exchange. This "people's bank" would furnish currency and credit at a low rate of interest, or none at all, against: (1) written orders for payment drawn by sellers of goods on the purchasers (acceptance bills); (2) payment bills issued to wage-earners by their employers; (3) credit bills presented by buyers of residential housing, industrial or agricultural property, who have been judged eligible for home loans or business loans. Thus Proudhon aimed to universalize the bill of exchange, an instrument of credit whose familiar use was in connection with the shipment of finished goods in commerce rather than in relation to home ownership or business-property transactions. Proudhon wished to divorce money and credit from any basis of gold or specie, so that the economy would constitute a universal credit union, with productivity rather than specie as the basis of credit. Labour and every product of labour would in effect be ready and exchangeable money. Because money in the form of goods or services cannot be hoarded, the aggregate supply of goods and services creates its own sufficient aggregate demand, hence unemployment caused by overproduction would be banished. With money based on productivity rather than specie, market competition would regulate prices so that consumers might buy goods at nearly their real costs of production; prices would not be burdened by surcharges of interest, rents, and capital gains realized by absentee capitalists, landlords, and speculators. Nor

can the government create money or manipulate its supply to favour politically powerful special-interest groups. For in Proudhon's scheme, money is only the reflection of productive transactions whose terms are negotiated by private producers without the intervention of government.

Besides his monetary reform proposals, Proudhon projected the concept of associations of owner-producers. Each association was to make its own internal rules; the members were to surrender individual advantages for the common good of the organization. A spirit of give-and-take was to characterize, in Proudhon's vision, the relations among the separate organizations of businessmen, workers and farmers. Thus mutualism within groups would join with mutuality between groups to yield an economy of justice—economic justice not stipulated by the government but justice emanating from the ranks of the producers.

Proudhon's economic reform program was early attacked by Karl Marx (*q.v.*), in 1847, on the ground that finance capitalism, which Proudhon sought to abolish, and industrial capitalism, which Proudhon wished to strengthen, are inextricably intertwined. In the Marxist view, the unplanned nature of capitalist production sets the stage for economic instability under which speculation thrives, as well as for concentration of economic power and exploitation of labour, so that Proudhon's desired working harmony among producers cannot be realized. This controversy—with Proudhon writing *The Philosophy of Misery* and Marx countering with *The Misery of Philosophy*—is of current interest. It exhibits the roots of the continuing difference between middle-class reformers and the would-be socialist transformers of capitalism.

A prolific and passionate writer, Proudhon analyzed in the manner of an unprofessional philosopher, and his writings frequently lapse into merely perceptive journalism, especially those in the field of national and international political affairs. Proudhon portentously combined a rebellious peasant provincialism with a global grandiosity—thus he presaged in his thoughts and deeds the persistently conflicting tendencies of French capitalist democracy, toward anarchy on the one hand and despotism on the other.

Proudhon's works in English translation include: *What Is Property? System of Economic Contradictions: or the Philosophy of Misery; General Idea of Revolution in the Nineteenth Century*. His complete works were published in Paris (1923–52). See also ANARCHISM; SOCIALISM.

PROUST, JOSEPH LOUIS (1754–1826), French chemist, whose great contribution to chemistry was his experimental establishment of the principle of the constant composition of compounds. Born at Angers on Sept. 26, 1754, he was the son of an apothecary. He studied chemistry under the direction of G. F. Rouelle, and became chief apothecary at the Salpêtrière Hospital in Paris. In his lifetime he attained eminence in chemistry in both France and Spain. In France he lectured at the Palais Royal, and in Spain he taught at the Academy of Artillery at Segovia, at the seminary at Vergara, and at the newly established Royal Laboratory at Madrid. The latter had notably excellent facilities, which enabled him to conduct (1799–1806) skilled researches on the composition of many substances, finally proving—beyond doubt that then existed—that pure compounds were strictly definite in composition by elements, no matter what their source. Thus his celebrated controversy with Claude Louis Berthollet (1748–1822) was resolved in Proust's favour. Proust did not formulate the law of definite proportions (John Dalton, 1808), but his work furnished the experimental evidence for its acceptance. After his election in 1816 to the French Academy of Sciences he returned to Angers where he died July 5, 1826.

Proust, a Frenchman, is frequently confused with William Prout (1785–1850), an Englishman. The latter was the proponent of the hypothesis in 1815 that the atomic weights of the elements are exact multiples of the atomic weight of hydrogen. (R. K. Sc.)

PROUST, MARCEL (1871–1922), French novelist whose *A la Recherche du Temps Perdu* (*Remembrance of Things Past*) is one of the supreme imaginative creations of world literature. He was born at Auteuil on July 10, 1871, the son of Adrien Proust, an eminent physician of provincial French Catholic descent, and his wife Jeanne, née Weil, of a wealthy Jewish family. After a first attack in 1880, he suffered from asthma throughout life. His childhood holidays were spent at Illiers and Auteuil, which together became the Combray of his novel, or at seaside resorts in Normandy with his maternal grandmother. At the Lycée Condorcet (1882–89), he wrote for class magazines, fell in love with a little girl named Marie de Benardaky in the Champs-Élysées, made friends whose mothers were society hostesses, and was influenced by his philosophy master Alphonse Darlu. He enjoyed the discipline and comradeship of military service at Orléans (1889–90) and studied at the École des Sciences Politiques under Henri Bergson (his cousin by marriage), Paul Desjardins, and Albert Sorel, taking "licences" in law in 1893 and in literature in 1895. Meanwhile, via the bourgeois salons of Mmes Straus, Arman de Caillavet, Aubernon, and Madeleine Lemaire, he became an observant *habitué* of the most exclusive drawing rooms of the nobility. In 1896 he published *Les Plaisirs et les jours*, a collection of short stories at once precious and profound, most of which had appeared during 1892–93 in the magazines *Le Banquet* and *La Revue Blanche*. From 1895 to 1899 he wrote *Jean Santeuil* (published 1952), an autobiographical novel which, though unfinished and ill-constructed, showed awakening genius and foreshadowed *A la Recherche*. A gradual disengagement from social life coincided with his concern about the Dreyfus affair (1897–99; see DREYFUS, ALFRED) and growing ill health. His discovery of Ruskin in 1899 caused him to abandon *Jean Santeuil* and to seek a new revelation in the beauty of nature and in Gothic architecture, considered as symbols of man confronted with eternity: "suddenly," he wrote, "the universe regained in my eyes an immeasurable value." On this quest he visited Venice (with his mother in May 1900), and the churches of France, and translated Ruskin's *Bible of Amiens* (1904) and *Sesame and Lilies* (1906), with prefaces in which the note of his mature prose is first heard.

The death of his father in 1903 and of his mother in 1905 left him grief-stricken and alone, but financially independent and free to attempt his great novel. At least one early version was written in 1905–06. Another, begun in 1907, and interrupted by a series of brilliant parodies of Balzac, Flaubert, Renan, Saint-Simon, and others of his favourite French authors, "L'Affaire Lemoine" (published in *Le Figaro*), through which he endeavoured to purge his style of extraneous influences, was laid aside in October 1908. Then, realizing the need to establish the philosophical basis which his novel had hitherto lacked, he wrote *Contre Sainte-Beuve* (published 1954), attacking the French critic's mandarin view of literature as a pastime of the cultivated intelligence, and putting forward his own, in which the artist's task is to release from the buried world of unconscious memory the ever living reality to which habit makes us blind. In January 1909 occurred the real-life incident of the involuntary revival of a childhood memory through the taste of tea and a rusk (later the famous "madeleine"); in May the characters of his novel invaded his essay; and in July of this crucial year he began *A la Recherche du Temps Perdu*. He thought of marrying "a very young and delightful girl" met at Cabourg, where he spent summer holidays from 1907 to 1914; but instead he retired from the world to write his novel, finishing the first draft in September 1912. After refusals from Fasquelle, the *Nouvelle Revue Française* and Ollendorff, *Du Côté de chez Swann*, the first volume, was published at the author's expense by Grasset in November 1913. Proust then planned only two further volumes, the premature appearance of which was fortunately thwarted by his anguish at the flight and death of his secretary Alfred Agostinelli, and by the outbreak of World War I.

During the war he revised the remainder of his novel, enriching and deepening its feeling, texture, and construction, increasing the realistic and satirical elements, and tripling its length. In this majestic process he transformed a work which in its earlier state was still below the level of his highest powers into one of

the profoundest and most perfect achievements of the human imagination. In March 1914, instigated by the repentant Gide, the *Nouvelle Revue Française* had offered to take over his novel, but Proust in turn rejected them. Further negotiations in May–September 1916 were successful, and in June 1919 *À l'Ombre des jeunes filles en fleurs* appeared simultaneously with a reprint of *Swann* and with *Pastiches et mélanges*, a miscellaneous volume containing "L'Affaire Lemoine" and the Ruskin prefaces. In December 1919, through Léon Daudet's recommendation, *À l'Ombre* received the Prix Goncourt and Proust suddenly became world famous. Three more installments appeared in his lifetime, with the benefit of his final revision: *Le Côté de Guermantes*, vol. 1 (October 1920), vol. 2, with *Sodome et Gomorrhe I* (May 1921); and *Sodome et Gomorrhe II* (3 vols., May 1922). He died in Paris on Nov. 18, 1922, of pneumonia, succumbing to the weakness of the lungs which many had mistaken for a form of hypochondria, and struggling to the last with the revision of *La Prisonnière*. The last three parts of *À la Recherche* were published posthumously, in an advanced but not final stage of revision: *La Prisonnière* in 1923, *Albertine disparue* (originally called *La Fugitive*, though the new title may well have had Proust's authority) in 1925, and *Le Temps retrouvé* in 1927.

The Novel: Plot.—*À la Recherche du Temps Perdu* is the story of Proust's own life told as an allegorical search for truth. At first the only childhood memory available to the middle-aged Narrator is the evening of a visit from the family friend Swann, when he forced his mother to give him the goodnight kiss which she had refused. Through the accidental tasting of tea and a madeleine cake he retrieves from unconscious memory the landscape and people of his boyhood holidays in the village of Combray. In an ominous digression on love and jealousy we learn the unhappy passion of Swann, a Jewish dilettante received in high society, for the courtesan Odette, met in the bourgeois salon of the Verdurins during the years before the Narrator's birth. As an adolescent the Narrator falls in love with Swann and Odette's daughter Gilberte in the Champs-Élysées. During a seaside holiday at Balbec he meets the handsome young nobleman Saint-Loup, Saint-Loup's strange uncle the baron de Charlus, and a band of young girls led by Albertine. He falls in love with the duchesse de Guermantes, but after an autumnal visit to Saint-Loup's garrison-town Doncières, is cured when he meets her in society. As he travels through the Guermantes world its apparent poetry and intelligence is dispersed, and its real vanity and sterility revealed. Charlus is discovered to be a homosexual, pursuing the elderly tailor Jupien and the young violinist Morel; and the vices of Sodomy and Gomorrah henceforth proliferate through the novel. On a second visit to Balbec the Narrator suspects Albertine of loving women, carries her back to Paris, and keeps her captive. He witnesses the tragic betrayal of Charlus by the Verdurins and Morel, and his own jealous passion is only intensified by the flight and death of Albertine. When he attains oblivion of his love Time is Lost, beauty and meaning have faded from all he ever pursued and won, and he renounces the book he had always hoped to write. A long absence in a sanatorium is interrupted only by a wartime visit to Paris, bombarded like Pompeii or Sodom from the skies. Charlus, disintegrated by his vice, is seen in Jupien's infernal brothel, and Saint-Loup, married to Gilberte and turned homosexual, dies heroically in battle. After the war, at the princesse de Guermantes' afternoon reception, the Narrator becomes aware, through a series of incidents of unconscious memory, that all the beauty he has experienced in the past is eternally alive. Time is Regained, and he sets to work, racing against death, to write the very novel we have just read.

The Novel: Structure, Meaning and Vindications.—Proust's novel has a circular construction, and must be considered in the light of the revelation with which it ends. Throughout a story which ostensibly tells of the irrevocability of Time Lost, the forfeiture of innocence through experience, the emptiness of love and friendship, the vanity of human endeavour, the triumph of sin and despair, the author has in fact reinstated the extratemporal values of Time Regained. Proust's subject is salvation, his message that the life of every day is supremely important, full of

moral joy and beauty which, though we lose them through faults inherent in human nature, are indestructible and recoverable. Other patterns of redemption are shown in counterpoint to the main theme: the Narrator's parents are saved by their natural goodness, great artists (the novelist Bergotte, the painter Elstir, the composer Vinteuil) through the vision of their art, Swann through suffering in love, even Charlus through the Lear-like grandeur of his fall. Proust's novel is, ultimately, both optimistic and set in the context of human religious experience. "I realised that the materials of my work consisted of my own past," says the Narrator at the moment of Time Regained. An important quality in the understanding of *À la Recherche* lies in its meaning for Proust himself as the allegorical story of his own life, from which its events, places, and characters are taken. In his quest for Time Lost he invented nothing, but altered everything, selecting, fusing, and transmuting the facts so that their underlying unity and universal significance should be revealed, working inward to himself and outward to every aspect of the human condition. *À la Recherche* is comparable in this respect not only with other major novels but with such creative and symbolic autobiographies as Goethe's *Dichtung und Wahrheit* and Chateaubriand's *Mémoires d'Outre-Tombe*, both of which influenced Proust.

Proust's projection of his own sexual inversion upon his characters is aesthetically justified by his use of this vice, parallel with snobism, vanity, and cruelty, as a major symbol of original sin. His insight into women and the love of men for women (which he himself experienced for the many female originals of his heroines) remained unimpaired, and he is among the greatest novelists of both normal and abnormal love. Other frequent charges against Proust are as misleading as those of pessimism, antireligion, or obsession with homosexuality. He has been thought idle, unproductive, weak-willed, corrupted by snobism, ill-equipped in philosophy, and absorbed in microscopic detail. In fact he worked unceasingly, prolifically, and with iron will from early youth, always in the direction of his great novel. He was an anti-snob with genuine interest in a brilliant and dying culture, a metaphysician with academic training and individual genius, and an impressionist whose detail is an imagery subordinated to the totality of his creation: "my instrument," he said, "is not a microscope, but a telescope directed upon Time." In general, hostile criticism of Proust, being based on a priori assumptions or on misuse of the biographical approach, has tended to reveal deficiencies not in Proust but in the scholarship or sensibility of its exponents.

Proust's Style, Influence, Reputation, Correspondence.

—Proust's mature prose style, although the remote inspiration of such varied precursors as La Bruyère, Saint-Simon, Chateaubriand, Balzac, Renan, and Ruskin, and of such contemporaries as Anatole France, Stéphane Mallarmé, Anna de Noailles, Francis Jammes, and Robert de Montesquiou is demonstrable, remains unique and self-engendered in its union of speed and protraction, precision and iridescence, force and enchantment, classicism and symbolism. His influence has indirectly affected the whole climate of the 20th-century novel, and is more directly visible in André Gide's *Les Faux-Monnayeurs*, Jacques de Lacretelle's *Silbermann*, Virginia Woolf's *The Waves*, and Anthony Powell's novel sequence *The Music of Time*. His reputation, though still imperfectly liberated from the superficial and semihostile assessments of the first generation of Proustian criticism, has always been safe with the general reader, and continues to rise toward its true level. A new critical tendency, in which Proust's work is considered sympathetically from within and on its own terms (cf. entries under G. Brée, H. Moss, R. Shattuck, and P. A. Spalding in the *Bibliography*), may well predominate in the final judgment.

Proust's enormous correspondence, of which more than 2,000 letters had been printed by 1964 and about twice as many more awaited publication, is remarkable for its elegance and nobility of style and thought, its communication of his living presence, and as one of the most significant exhibitions in all literature of the raw material from which a great artist built his universe.

BIBLIOGRAPHY.—*Editions and Translations.*—The standard text of *À la Recherche* is the Pléiade edition, by P. Clarac and A. Ferré,

3 vol. (1954). C. K. Scott-Moncrieff's translation, *Remembrance of Things Past*, 12 vol. (1922–31; vol. 12, *Time Regained*, trans. by S. Hudson [pseudonym of S. Schiffl], also in U.S. as *Past Recaptured*, 1932, trans. by F. A. Blossom), is an English classic. Other excellent translations are *Jean Santeuil* (1955) and *Miscellaneous Writings* (1948), by G. Hopkins; *By Way of Sainte-Beuve*, by S. Townsend Warner (1958); *Pleasures and Regrets*, by L. Varèse (1948); *Letters of M. Proust*, by M. Curtiss (1950). PROUSTITE, a mineral consisting of silver sulfarsenite, known also as light red silver ore, and an important source of the metal. It is closely allied to the corresponding sulfantimonite, pyrargyrite (*q.v.*), or dark red silver ore, from which it was distinguished by the chemical analyses of J. L. Proust in 1804, after whom the mineral received its name. The composition is Ag_3AsS_3 . The colour is scarlet-vermilion and the lustre adamantine; crystals are transparent and very brilliant, but on exposure to light they soon become dull black and opaque. The streak is scarlet, the hardness 2.5, and the specific gravity 5.57.

The mode of occurrence is the same as that of pyrargyrite, although proustite is less common, and the two minerals are sometimes found together. Magnificent groups of large crystals have been found at Chañarcillo in Chile; other localities which have yielded fine specimens are south Lorrain, Ont., and Freiberg and Marienberg in Saxony. It is mined as an ore in Mexico and is found in small amounts in the United States in California, Colorado, Idaho and Nevada.

PROUT, SAMUEL (1783–1852), English water colourist, born at Plymouth, Devon, Sept. 17, 1783, was educated at Plymouth grammar school. He went on sketching expeditions with B. R. Haydon, at whose father's house he met John Britton, publisher of *The Beauties of England and Wales*. He worked for Britton in London, and exhibited at the 1803 Royal Academy. He also painted marine pieces for T. Palser, received pupils, and in 1813 published *The Rudiments of Landscape, With Progressive Studies*, the first of his several handbooks for art students. From 1815 he exhibited regularly at the Water-Colour society, becoming a member four years later. A visit to France in 1819 distinguished him from previous English topographers by his choice of foreign townscapes as subjects, and that same year he attempted the recently discovered process of lithography. His *Illustrations of the Rhine* (1824) comprised the first of many lithographs resulting from frequent visits to France, Germany, the Netherlands and Italy. He died at Camberwell, Feb. 10, 1852. Prout's success was due to his fine draftsmanship, skillful composition and ability to seize upon some strikingly picturesque quality.

See Jane Quigley, *Prout and Roberts* (1926). (D. L. Fr.)

PROVENÇAL LANGUAGE is one of the Romance languages (*q.v.*). In its narrow meaning the term refers to the speech, or the dialects, of the region called Provence. But more

often it is the collective term for all southern dialects of France. Similarly the alternative name *langue d'oc* (*oc* "yes," as compared with northern *oil*, modern *oui*) refers generally to all idioms of the Midi (the south), although Languedoc as a politico-geographic term signifies only part of the region. In literary history, however, Provençal is the name given to the artificially homogeneous standard language employed by the troubadours (*q.v.*) of the 12th, 13th and 14th centuries.

The boundary separating Provençal (in the widest sense) from northern French runs from the estuary of the Gironde eastward along the northern edge of the Massif Central, crosses the Rhone between Vienne and Valence, and moves toward the Alps; but in the middle ages the frontier lay much farther to the north, being anchored in the west at the mouth of the Loire and in the east in the southern Vosges mountains.

This linguistic boundary, which is so trenchant as to be one between languages rather than dialects, resulted from differing historic and cultural developments. The Midi, or at least part of it, was conquered by the Romans in 122 B.C., about 70 years before the rest of Gaul. A flourishing and rich province, it was quickly and profoundly romanized. Moreover, the Germanic invasions of the middle ages were culturally less effective than they were in the north; even that of the Franks (so decisive elsewhere as to give their name to the whole country) exerted little influence. The southern dialects, in comparison with the northern, are therefore more conservative in their retention of Latin traits and less affected by the Germanic superstratum.

The medieval history of the Midi is that of many small feudal holdings in constant dispute among themselves and with outsiders. The country never attained national independence, but it was officially united with the rest of France in 1486. The greatest single catastrophe to befall the south was the crusade against the Albigenses (see CATHARI) early in the 13th century. What began as a religious expedition under the aegis of the church against the Albigensian heresy ended as political suppression of the south and its feudal lords by northern competitors. This calamity brought about the end of the independent flourishing of the Midi's native culture, particularly of its troubadour literature; it was assuredly responsible for the end of Provençal as an interregional standard idiom, for the re-emergence of local dialects, and for the spread, albeit slow, of standard northern French, in particular Francien, the dialect of the Île-de-France, as the literary and official language of the whole region.

Henceforth the southern dialects, bereft of a southern standard language in competition with Francien, sank to the level of patois of strictly local and familiar currency. The present dialects may be classified as follows: (1) Provençal (in the narrow sense as idioms of the Provence proper); (2) Auvergnat and Limousin; (3) Gascon (see below). Each of these larger divisions can of course be subdivided into smaller dialects, in the past as much as, or even more than, now.

This dialectal fragmentation of the south raises the question as to which of the southern dialects was employed in troubadour poetry, or which formed the core of their fairly homogeneous language. The main obstacle to a satisfying answer, apart from the insufficient knowledge of the medieval dialects of the Midi, is that Provençal, even in the works of the oldest troubadours (Gui-

hem IX, Marcabrun, Cercamon), is already fully developed and standardized, so that the history of its formation escapes linguistic scrutiny. On the whole, it seems to represent a central rather than a peripheral southern speech area. The history of the Provençal language largely deals with the language of the troubadours since little else is known until recent times. It is convenient to compare it with the northern Francien standard in order to show its peculiarities. See also FRENCH LANGUAGE and, especially for earliest developments from Latin, ROMANCE LANGUAGES.

Where northern dialects nasalize a vowel before a following *m* or *n*, with eventual absorption of the consonant (*pontem* > *pō*), Provençal may not nasalize at all, or may nasalize the vowel with retention of the consonant (*pontem* > *pon*, *pōn*).

Gascon has certain peculiarities which set it apart from other southern dialects. For example, Latin medial *-ll-* appears as *-r-* (*appellare* > *apera*[*r*]), final *-l* as *-t* (*bell[um]* > *bet*), initial *r-* as *arr-* (*ramu[m]* > *arram*), initial *f-* as *h-* (*femina* > *hemna*, *hemmo*). For these and other reasons some do not include Gascon among the Provençal dialects (in the wider sense). But then the only alternative is to establish it as a separate Romance language, as some linguists do with Catalan or Franco-Provençal or both.

In morphology, the declension of Old Provençal retains, as does Old French, a two-case system, one for the subject and one for the nonsubject case. In the modern dialects, a one-case (that is, no-case) system prevails.

The Provençal verb partakes of all the changes from Latin to Romance in general; but the typically Provençal features relate it more to Ibero-Romance (Spanish, Portuguese, Catalan; *q.v.*) than to French.

A renaissance of southern speech ways was unsuccessfully attempted during the 19th century, mainly through the efforts of Frédéric Mistral (*q.v.*), who attempted to create a new literary standard language for the Midi, based chiefly on several patois of the Bouches-du-Rhône district.

PROVENÇAL LITERATURE (*i.e.*, the literature written in the Oc-speaking southern France and, for a limited period, in Italian and Spanish cultural dependencies; see PROVENÇAL LANGUAGE) can be clearly divided into three periods: the first, a period of unity during which a literary language called "classic Provençal" was universally written, if not spoken (11th-15th century); the second, a period of dispersion in which a variety of provincial dialects were developed (16th-18th century); and the third, a period of partial recovery (19th-20th century).

FIRST PERIOD

Origins.—The new vernacular literature took a poetic form, and its oldest monuments show a virtuosity and a variety that indicate that poetry had already been practised for some time. The oldest piece of Provençal verse extant, a refrain attached to a Latin poem in a Vatican manuscript, is said to belong to the 10th century. More important, however, is a 257-line fragment of didactic verse preserved in an Orléans manuscript and frequently edited since F. J. Raynouard first printed it in his *Choix des poésies originales des troubadours* (1816-21). It is the beginning of an adaptation of Boëthius' treatise *De Consolatione Philosophiae* by an anonymous clerk. The handwriting of the manuscript is that of the period A.D. 1000-50; the language seems to belong most probably to the Limousin or to the Marche. A little later on, at the close of the 11th century, we have the poems of William IX, duke of Aquitaine (Guilhem VII of Poitiers). They consist of 11 very diverse strophic pieces and were meant to be sung. Several are love songs; one relates a *bonne fortune* in very free terms; and the most important of all, of about 1119, expresses in touching and often noble words the writer's regret for the frivolity of his past life and the apprehensions which oppressed him as he bade farewell, perhaps forever, to his country and his young son.

There is no reason to believe that William created the type of poetry of which he is to us the oldest representative: it may have been his high rank that saved some of his work from oblivion while that of his predecessors and contemporaries disappeared. The contrast in form and subject between Boëthius' poem and the stanzas of William IX is an indication that by the 11th century Provençal poetry was being rapidly developed in various directions. Whence came this poetry? How and by whose work was it formed? The view which seems to meet with general acceptance (even if a slight influence from Arabic poetry is admitted) is that Romance poetry sprang out of a popular poetry quietly holding its place from Roman times. Gradually the poets must have found themselves obliged to compound with the refinement of an aristocracy that had become, from century to century, more and more refined.

From what class of persons did this poetry proceed? Latin chroniclers of the middle ages mention *ioculares*, *ioculatores*, men of a class not very highly esteemed whose profession consisted in amusing their audience either by what we still call jugglers' tricks, by exhibiting performing animals, or by recitation and song. They were called *joglars* in Provençal, *jonglers* or *jongleurs* in French. From among them rose the troubadours (*q.v.*) who originally may have been *joglars* skilled in poetry, thence mere poets staying at a court or riding from castle to castle with a common *joglar* as a performer and companion.

The Provençal love songs reflect the social conditions obtaining in the Midi under feudalism. The daughters of territorial lords, who might well become rich heiresses, were married for political reasons, not to satisfy their own inclinations; but, once married, they seem to have enjoyed a very generous measure of personal liberty. Consequently, they welcomed the attentions of their husbands' dependents, who, as courtiers, would address flattering songs of love to them. As the poets were usually far beneath the ladies in social status, they wrote in a most guarded and respectful style, as though they had very little hope of having their love requited. This profession of "courtly" or "chivalrous" love became a matter of convention (see COURTLY LOVE); but it would be a mistake to assume that the real sentiments or experiences were invariably as platonic as the expression given to them.

The Troubadours.—By the end of the 11th century a clear distinction had been drawn between the lower sort of *joglars* and the refined poets; and it is to the poets as such that the name troubadour belongs, comprising as it does not only accomplished poets of the lower ranks of society but also some of the great nobles who wrote poetry. In the Limousin lived a viscount of Ventadour, Eble II, who early in the 12th century seems to have been brought into relation with William IX of Aquitaine and, according to a contemporary historian, Geffrei, prior of Vigéois, *erat valde graciosus in cantilenis* ("he was a composer of very graceful songs"). We possess none of his compositions; but under his influence Bernart de Ventadour was trained to poetry. Bernart gained the love of the lady of Ventadour and, when on the discovery of their amour he had to depart elsewhere, received a gracious welcome from William IX's granddaughter Eleanor of Aquitaine, consort (from 1152) of Henry II of England. Of Bernart's compositions we possess about 50 songs of elegant simplicity; some of which may be taken as the most perfect specimens of Provençal love poetry. At the same period, or earlier, flourished Cercamon, a Gascon, who composed, says his old biographer, "pastorals according to the ancient custom" (*pastorelas a la uzansa antiga*). Among the earliest troubadours is Marcabrun, a pupil of Cercamon's, from whose pen we have about 40 pieces, those which can be approximately dated ranging from about 1135 to about 1148. His songs, several of which are concerned with contemporary history, are free from the commonplaces of their class, and contain curious strictures on the corruptions of the time. Jaufré Rudel of Blaye, the singer of the *amor de lonh* (far-away love), is scarcely less famous.

Only a few of the troubadours can be cited here. They include Peire d'Alvernhae, Raimbaut III d'Orange, Béatrix de Die, Arnaut Daniel (remarkable for his complicated versification and the inventor of the *sestina*), Arnaut de Mareuil (less famous than

Arnaut Daniel, but surpassing him in elegant simplicity of form and delicacy of sentiment), Bertran de Born (famous for the part he is said to have played both with his sword and his *sirventès* in the struggle between Henry II of England and his rebel sons), Peire Vidal of Toulouse (a poet of varied inspiration who grew rich with gifts bestowed on him by the greatest nobles), Giraut de Bornelh, or Guiraut de Bornelh (*lo maestre dels trobadors* and acknowledged master of *trobar clus* or "close" style, though he also composed songs of charming simplicity), Gaucelm Faidit (who wrote a touching lament or *planh* on the death of Richard Cœur de Lion), Folquet de Marseille (who from being a troubadour became first a monk, then an abbot, and finally bishop of Toulouse), the chivalrous Raimbaut de Vaqueyras, the truculent monk of Montaudon, the satirical Peire Cardenal, and "the last troubadour," Guiraut Riquier. Of lesser importance, but still to be remembered among the 460 troubadours whose works exist, are: Peire Rogier, Peire Raimon, Raimon de Miraval, Aimeric de Pegulhan, Rigaut de Barbezies, Guiraut de Calanson, Uc de Saint-Circ, Peirol, Perdigon, Cadenet, Guilhem Figueira, Montan-hagol, Folquet de Lunel, Bertran Carbonel, Elias de Barjols, Bertran de Lamanon, Pons de Chapeuil, Cerveri de Girone, Bonifacio Calvo, Sordello.

The troubadours who were not themselves great feudatories could hardly expect to obtain a livelihood from any quarter other than the generosity of the great. It will consequently be well to mention the most important at least of those princes who are known to have been patrons and some, indeed, themselves poets: in France, Eleanor of Aquitaine, Henry Curtmantle, Richard Cœur de Lion, Ermengarde of Narbonne, Raymond V and Raymond VI of Toulouse, Alfonso II and Raymond Berengar IV, counts of Provence, Barral de Baux, William VIII, lord of Montpellier, Henri I, Hugh IV and Henri II, counts of Rodez; in Spain, Alfonso II and Pedro II, kings of Aragon, Alfonso IX and Alfonso X, kings of Castile; in Italy, Boniface I, marquis of Montferrat, Frederick II, emperor, Azzo VI and Azzo VIII, marquis of Este. These are a few only of the great patrons.

The decline and fall of troubadour poetry was due mainly to political causes. When in the first decades of the 13th century the Albigensian War had ruined a large number of the nobles and reduced to lasting poverty a part of the Midi, the profession of troubadour ceased to be lucrative. It was then that many of these poets went to spend their last days in the north of Spain and Italy, where Provençal poetry had for more than one generation been highly esteemed. Following their example, other poets who were not natives of the Midi began to compose in Provençal; but from the middle of the 13th century, they began to abandon the foreign tongue and took to singing the same airs in the local dialects. About the same time in the Midi itself the flame of poetry had died out save in a few places—Narbonne, Rodez, Foix, and Astarac—where it kept burning feebly for a little longer. In the 14th century composition in the language of the country was still practised; but the productions of this period are mainly works for instruction and edification. The poetry of the troubadours was dead. See further TROUBADOURS.

Chansons de Geste and Historical Poems.—Northern France is *par excellence* the country of the *chanson de geste* (q.v.); but Provençal literature has some highly important specimens of the class. The first place belongs to *Girart de Roussillon*, a poem of 10,000 lines, which relates the struggles of Charles Martel with his powerful vassal Gerard of Roussillon. The existing recension seems to have originated on the borders of Limousin and Poitou; but it is a recast of an older poem no longer extant, probably either of French or at least Burgundian origin. To Limousin also seems to belong the poem *Aigar e Maurin* (end of the 12th century). Of less heroic character is the poem *Daurel e Beton* (first half of the 13th century).

Midway between legend and history may be classified the Provençal *chanson* on the siege of Antioch, a mere fragment of which, 700 verses in extent, was recovered in Madrid and published in *Archives de l'Orient latin*, vol. ii (1884). This poem (see G. Paris, *Romania*, xxii, 358, 1893) is one of the sources of the Spanish compilation *La Gran Conquista de Ultramar*. To history proper

belongs the *chanson* of the crusade against the Albigensians, which, in its present state, is composed of two poems, one tacked to the other: the first, containing the events from the beginning of the crusade till 1213, is the work of a cleric named Guilhem de Tudela, a moderate supporter of the crusades; the second, from 1213 to 1218, is by a vehement opponent of the enterprise. The language and style of the two parts are no less different than the opinions. The second part is certainly one of the masterpieces of Provençal literature. Finally, about 1280, Guilhem Anelier, a native of Toulouse, composed a poem on the war carried on in Navarre by the French in 1276 and 1277, a historical work of little literary merit. All these poems are in the form of *chansons de geste*; that is, in stanzas of indefinite length, with a single rhyme. *Girart de Roussillon*, *Aigar e Maurin*, and *Daurel e Beton* are in lines of 10, the others in lines of 12, syllables. The peculiarity of the versification in *Girart* is that the pause in the line occurs after the sixth syllable and not, as is usual, after the fourth.

Narrative Poems.—We possess only three Provençal romances of adventure: *Jaufré* (composed in the middle of the 13th century and dedicated to a king of Aragon, possibly James I), *Blandin de Cornalha* and *Guillem de la Barra*. Connected with the romance of adventure is the novel (in Provençal *novas*, always in the plural), which is originally an account of an event "newly" happened. Some of the extant novels may be ranked with the most graceful works in Provençal literature. Two are from the pen of the Catalan author Ramon Vidal de Besalú: one, the *Castia-gilos*, is an elegant treatment of the story of the husband who disguises himself as his wife's lover in order to trap her and receives with satisfaction blows intended, as he thinks, for him whose part he is playing; the other is the recital of a question of the law of love, departing considerably from the subjects usually treated in the novels. Mention may also be made of *Novas del Papagai* by Arnaut de Carcassès, in which the principal character is an eloquent parrot, who assists the amorous enterprises of his master. Novels came to be extended to the proportions of a long romance. *Flamenca*, which belongs to the novel type, still runs to more than 8,000 lines, though the only manuscript of it has lost some leaves both at the beginning and at the end. This poem, composed in all probability in 1234, is the story of a lady who by very ingenious devices, not unlike those employed in the *Miles gloriosus* of Plautus, eludes the vigilance of her jealous husband. No book in medieval literature betokens so much quickness of intellect or is so instructive in regard to the manners and usages of polite society in the 13th century.

Didactic and Religious Poetry.—The more important works are: the Boëthius poem (unfortunately a mere fragment), already mentioned as one of the oldest documents of the language; an early (12th-century?) metrical translation of the *Disticha de moribus* of Dionysius Cato; Daude de Prades' *Ausels cassadors* (early 13th century), one of the best sources for the study of falconry; and a translation by Raimon d'Avignon (c. 1200) of Roger de Parme's "Surgery." More original are some compositions of an educational character known under the name of *ensenhamens*. The most interesting are those of Garin le Brun (12th century), Arnaut de Mareuil, Arnaut Guilhem de Marsan, Amanieu de Sescas. Their general object is the education of ladies of rank. Of metrical lives of saints we possess about a dozen, among which two or three deserve particular attention: the life of St. Fides (ed. by A. Thomas and by E. Hoepfner, 1916), written early in the 13th century; the life of St. Enimie (13th century), by Bertran of Marseilles (ed. by C. Brunel, 1916) and that of St. Honorat of Lerins by Raimon Feraut (about 1300), which is distinguished by variety and elegance of versification but is almost entirely a translation from Latin. Lives of saints (St. Andrew, St. Thomas the Apostle, St. John the Evangelist) form a part of a poem, strictly didactic, which stands out by reason of its great extent (nearly 350 verses) and the somewhat original conception of its scheme—*Breviari d'amor*, a vast encyclopaedia on a theological basis, composed c. 1288–1300 by the Minorite friar Matfre Ermengaud of Béziers.

Drama.—The dramatic literature of the Midi consists of mysteries and miracle plays seldom exceeding 2,000 or 3,000

which never developed into the enormous dramas of northern France, whose acting required several consecutive days. Generally these plays belong to the 15th century or to the 16th. Still, a few are more ancient and may be ascribed to the 14th century or even to the end of the 13th. The oldest appears to be the *Mystery of St. Agnes* (edited by K. Bartsch, 1869), written in Arles. Somewhat more recent, but not later than the beginning of the 14th century, are a mystery on the Passion of Christ and another on the Marriage of the Virgin; the latter is partly adapted from a French poem of the 13th century. A number of mysteries written in Rouergue, Provence, and Dauphiné, more or less connected with French patterns, are practically void of interest.

Prose.—In the 12th century we find in Languedoc sermons whose importance is more linguistic than literary (*Sermons du XII^e siècle en vieux provençal*, ed. by F. Armitage, 1884). About the same time, in Limousin, were translated ch. xiii–xvii of St. John's Gospel (K. Bartsch, *Chrestomathie provençale*, 1855–1904). Various translations of the New Testament and of some parts of the Old were made in Languedoc and Provence during the 13th and 14th centuries (see S. Berger, "Les Bibles provençales et vaudoises," *Romania*, xviii, 353, 1889; and "Nouvelles recherches sur les Bibles provençales et catalanes," *ibid.*, xix, 505, 1890). The Provençal prose rendering of some lives of saints made in the early part of the 13th century (*Revue des langues romanes*, 1890) is also more interesting from a linguistic than from a literary point of view. To the 13th century belong certain lives of the troubadours intended to be prefixed to, and to explain, their poems. Many of them were written before 1250, when the first anthologies of troubadour poetry were compiled; and some are the work of the troubadour Uc de Saint Circ. Some were composed in the north of Italy, at a time when the troubadours found more favour east of the Alps than in their own country. Considered as historical documents these biographies are of a very doubtful value. To the same period must be assigned *Las Razos de trobar* of the troubadour Ramon Vidal de Besalú (an elegant little treatise touching on various points of grammar and the poetic art), the *Donatz proensals* of Uc Faidit and the "life" of St. Douceline, who died in 1274, near Marseilles, and who founded an order of Beguines.

The leading prose work of this period is the treatise on grammar, poetry, and rhetoric known by the name of *Leys d'amors*, composed in Toulouse c. 1350. The decay of Provençal literature, caused by political circumstances, arrived too soon to allow of a full development of prose. Nor did anything remain, in the second quarter of the 14th century, of what had been the first Provençal classicism, except in Toulouse. There, the conventional poetry was preserved, from 1324, by the *Consistori del set mantene dors del gay sabor*, the original form of the Collège de Rhétorique, whence developed the Académie des Jeux-Floraux.

SECOND PERIOD

Owing to this, Provençal literature never died out entirely—although its life was not brilliant. The poets crowned by this body up to 1498 stand in the same relation to the troubadours as the *Meistersinger* do to the *Minnesinger* (q.v.): academic correctness takes the place of inspiration. The institution flourished, even to the extent of establishing branches in Catalonia and Majorca; and in 1484, when its prosperity was threatened, a semisfabulous person, Clémence Isaure, is said to have brought about a revival by instituting fresh prizes. The town of Toulouse never ceased to supply funds of some kind. In 1513 French poems were first admitted in the competitions, and under Louis XIV (from 1679) these were alone held eligible. This arrangement held good till 1893, when the town very properly transferred its patronage to a new *Escolo moundino*; but it soon restored its support to the older institution, on learning that Provençal poetry was again to be encouraged. In the two centuries that followed the glorious medieval period we have a succession of works, chiefly of a didactic and edifying character, which served to keep alive some kind of literary tradition. Religious mystery plays, which, though dull to us, probably gave keen enjoyment to the people, represent a more popular genre.

In the 16th century there are not only signs of a revival, but a strong movement toward what might be called a Provençal Renaissance. The Gascon Pey de Garros (1525?–85), author of the remarkable *Eglogues*, raised his native dialect to the rank of a literary language with his translation of the Psalms of David (1565) and inserted in his *Poesias gasconas* (1567) a manifesto that might be compared to the Declaration of Font-Ségugne, launched four centuries later by the *Felibres* (see below, *Third Period*). As early as 1579, G. de Salluste du Bartas, in his trilingual *Salut or Poème pour l'accueil de la Reine de Navarre*, followed the example of Pey de Garros. The Rabastens wheelwright, Augié Gaillard (1530–92), started the movement in Languedoc, and Louis Bellaud de la Bellaudière (1532–88) in Provence proper.

After Garros, in Gascony, came Guillaume Ader (1578–1638; *Lou Catounet gascon*, 1612; *Lou Gentilome gascon*, 1610), Louis Baron (1612–63), who celebrated with great tenderness his native village of Pouylouburin, Géraud Bedout (1617–93; *Lou Parterre gascon*, 1642), and J. G. d'Astros who, about the same time, with his remarkable *Trinfe de la lengouo gascon*, proved a most elegant and witty verse writer. But the most conspicuous among the poets of the Midi between Pey de Garros and Jacques Jasmin is certainly Pierre Goudelin (Goudouli; 1579–1649) of Toulouse, "the Malherbe of Oc," who, had he written in French, would be ranked with the best poets of the period. Nicolas Saboly (1614–75) excelled in the popular form known as the *noël*.

Other 17th-century writers worth mentioning, outside Gascony, are Claude Brueys (1580–1650), remarkable chiefly for comedies dealing with duped husbands (e.g., *Jardin deys Musos Provensals*, 1628); Gaspar Zerbin (*La Perlo deys Musos et comedies provensals*, 1655); Jean Michel de Nîmes, who wrote the picturesque *Embarras de la Fieiro de Beaucaire*; Daniel Sage of Montpellier (*Las Foulies*, 1650); the *avocat* Bonnet, author of the best among the open-air plays that were annually performed at Béziers on Ascension Day (a number of these, dated 1616–57, were subsequently collected, but none can compare with the opening one, Bonnet's *Jugement de Paris*); Nicolas Fizes, of Frontignan, whose vaudeville, the *Opéra de Frontignan* (1679), dealing with a slight love intrigue, and an idyllic poem on the fountain of Frontignan, show a real poetic gift. A number of Toulouse poets, mostly *lauréats* of the academy, may be termed followers of Goudelin: of these, François Boudet, who composed an ode, *Le Trinfe del Moundi* (1678), in honour of his native dialect, deserves mention. The classical revival that may be noted about this time is also generally ascribed to Goudelin's influence. Its most distinguished representative was Jean de Valès, of Montech, who made excellent translations from Virgil and Persius and wrote a brilliant burlesque of the former in the manner of Scarron (*Virgile deguisat*, 1648).

The best of the pastoral poets was François de Cortète (1585/86–1667), of Prades, whose comedies, *Ramounet* and *Miramoundo* (published, unfortunately with alterations, by his son in 1684), are written with such true feeling and in so pure a style that they can still be read with pleasure. Arnaud Daubasse (1664–1727), of Quercy, who belonged to the working classes, was patronized by the nobility in exchange for panegyrics.

In the 18th century the number of authors is much larger, but the bulk of good work produced is not equally great in proportion. The priests are mainly responsible for the literary output of Languedoc. The chief of the band is the abbé J. B. Favre (1727–83), whose *Sermoun de Moussu Sistre*, delivered by a drunken priest against intemperance, is a masterpiece. He also wrote a successful mock-heroic poem (*Lou Siège de Cadaroussa*), travesties of Homer and Virgil, a prose novel depicting the country manners of the time (*Histouèro de Jan-l'an-pres*) and two comedies which give a vivid picture of the village life that he knew so well. Two genuine poets are the brothers Rigaud of Montpellier: Auguste (1760–1835) was the author of a deservedly famous description of a vintage; and Cyrille (1750–1824) produced an equally delightful poem on the *Amours de Mounpèié*. Pierre Hellies of Toulouse (d. 1724), a poet of the people, whose vicious life finds an echo in his works, has a certain rude charm, at times distantly recalling Villon. In Provence, Toussaint Gros (1698–1748), of Lyons, holds undisputed sway. His style and language

are admirable, but unfortunately he wasted his gifts largely on trivial *pièces d'occasion*. J. B. Coyer's (1711-70) comedy, *Lou Novy para*, is bright and still popular, while J. B. Germain's (d. 1781) description of a visit paid by the ancient gods to Marseilles (*Bourrido dei Dious*, 1768) has considerable humour. In Gascony the greatest poet is Cyrien Despourrins (1698-c. 1756).

THIRD PERIOD

The Revolution produced a large body of literature, but nothing of lasting interest. When it was over, scholars like F. J. Raynouard (1761-1836), of Aix, occupied themselves with the brilliant literary traditions of the Middle Ages; newspapers sprang up (the Provençal *Bouil-Abaisso*, started by Joseph Désanat, and the bilingual *Lou Tambourin et le menestrel*, edited by Pierre Bellot, both in 1841); poets banded together and collected their pieces in volume form (e.g., the nine *troubaire* who published *Lou Bouquet prouvençaou* in 1823). Much has been written about the "forerunners of the Félibrige," and critics are sorely at variance as to the writers that most deserve this appellation. We shall not go far wrong if we include in the list Hyacinthe Morel (1756-1829); Louis Aubanel (1758-1824); Auguste Tandon (1759-1824), "the troubadour of Montpellier"; Antoine Fabre d'Olivet (1767-1825); J. J. M. Diouloufet (1785-1840); Jacques Azais (1778-1856); Léon d'Astros (1780-1863); F. H. J. Castil-Blaze (1784-1857); the marquis de la Fare-Alais (1791-1846). While these writers were all more or less academic and appealed to the cultured few, four poets of the people addressed a far wider public: Antoine Verdié (1779-1820), of Bordeaux, who wrote comic and satirical pieces; Jean Reboul (1796-1864), the baker of Nîmes, who never surpassed his first effort, *L'Ange et l'enfant* (1828); Victor Gelu (1806-85), relentless and brutal but undeniably powerful of his kind (*Fenian et Grouman; dix chansons provençales*, 1840); and, greatest of them all, the true and acknowledged forerunner of the Félibres, Jacques Jasmin (q.v.).

The Advent of the Félibrige.—In 1845 Joseph Roumanille (1818-91) of Saint-Rémy became usher in a small school of Avignon, which was attended by Frédéric Mistral (q.v.). Roumanille had composed some pieces in French; but, finding that his old mother could not understand them, he determined thenceforth to write in his native dialect only. These poems revealed a new world to young Mistral and spurred him on to the resolve that became the one purpose of his life: "to stir this noble race, which Mirabeau in mid-'89 still called the Provençal nation, to a renewed awareness of its glory." There is no doubt that Mistral's is the more powerful personality or that his finest work towers above that of his fellows; but in studying the Provençal renaissance, Roumanille must not be overlooked: his claims, indeed, were put forward with great force by Mistral himself (in the preface of *Lis Isclo d'our*). Roumanille's secular verse (*Li Margarideto*, 1836-47; *Li Sounjarello*, 1852; *Li Flour de Sauvi*, 1850-59, etc.) moves the reader with the sincerity of its poetry, his *noëls* are second only to those of Nicolas Saboly, his prose works (such as *Lou Mege de Cucugnau*, 1863) sparkle with delightful humour. He it was who in 1852 collected and published *Li Prouvençalo*, an anthology in which all the names yet to become famous and most of those famous already (such as Jasmin) are represented. In 1853 he was one of the enthusiastic circle that had gathered round J. B. Gaut at Aix, whose literary output is contained in the *Roumanvagi deis troubaires* (1853) and in the shortlived journal *Lou Gay Saber* (1854). At the same time the first attempt at regulating the orthography of Provençal was made by him (in the introduction to his play, *La Part dou bon Dieu*, 1853). In 1854 he was one of the seven poets who, on May 21, foregathered at the castle of Font-Ségugne, near Avignon, and founded the Félibrige. The other six were Mistral, Aubanel, A. Mathieu (a schoolfellow of Mistral's at Avignon), J. Brunet, A. Tavan, and P. Giera (owner of the castle). Of these, Théodore Aubanel (1829-86; of Avignon, son of a printer and following the same calling) alone proved himself worthy to rank with Mistral and Roumanille. "Zani," the girl of his youthful and passionate love, took the veil; and this event cast a shadow over his whole life and determined the character of all his poetry (*La Miougrano entre duberto*, 1860; *Li Fihò*

d'Avignon, 1885). His is, without a doubt, the deepest nature and temperament among the Félibres, and his lyrics are the most poignant.

The Félibrige After Roumanille, Aubanel, and Mistral.—The Félibrige increased considerably in the period after Mistral. The names of A. B. Crousillat, L. Roumieux, and of the "Muse" Antoinette de Beaucaire should be added to those of the signatories of the Font-Ségugne declaration. In Catalonia, V. Balaguer (q.v.) lent his glory to the movement's development, even before he joined it. Among poets of the next generation, the most illustrious is Félix Gras (1844-1901), who, as a young man, settled at Avignon. His rustic epic, *Li Carboundié* (1876), is full of elemental passion, and abounds in fine description. Gascony, which had been less closely associated with the Félibrige, admitted the Landais writer I. Salles (1821-1900) among the heirs of Despourrins and the earlier Xavier Navarrot (1799-1862). Quite independent were Auguste Fourès (1848-91) in Languedoc and Clovis Hugues (1851-1907) and Auguste Marin (1861-1904) at Marseilles. The Latin Félibrean movement developed in Montpellier with A. Roque-Ferrier (1844-1907), and the Federalist movement with F. Amouretti (1863-1903) and Marius André (*La Glòri d'Esclarmoundo*, 1894; *Eme d'orange un cargamen*, 1924). Among the wider heritage of the first Félibres should also be mentioned the Irishman Bonaparte Wyse (1826-92; *Li Piado de la Princesso*, 1882); the popular songwriter Charles Rieu (Charloun; 1845-1924); and, with poets born in Gascony (J. Noulers), Rouergue (J. Bessou), and Languedoc (A. Maffre), the somewhat artificial Joseph Roux (*La Chanson Lemousina*, 1889), and the Auvergnat Arsène Vermeuouse, who, with his *Flour de Broussou* (1895) and *Jous la Chuchado* (1908), proved one of the poets most evocative of his homeland. Among those who became famous during the first half of the 20th century should be mentioned Valère Bernard (1860-1936), of Marseilles (*La Legenda d'Esclarmounda*, 1936), Prosper Estieu (1860-1939), Antonin Perbosc (1861-1944), the Languedocian poet of *Lo Got Occitan* (1903), Michel Camélat of Bigorre, Simin Palay of Béarn, and the Pyrenean *troubairitz* Philadelphe de Gerde. Contemporary with them were the *meynadiers* of the Camargue in Provence proper: Joseph d'Arbaud (1872-1950), who is less famous as the poet of *Lou Lausé d'Arle* (1913) than as author of such short stories as *La Bestiou dou Vacarès* written in an epic vein; Folco de Baroncelli (1869-1943); and Marius Jouveau (1878-1949). A curious case is that of S. A. Peyre (1890-1961), writing in Provençal, in French, and in English. Had Paul Froment (1875-98) not died young, he would probably have been the great poet of Quercy, but this place was taken by the bucolic and religious poet Jules Cubaynes (1894-). P. L. Grenier (1879-1954) was a notable artist who revived the classical language of Limousin. J. B. Chèze, in the same region, wrote the delicate *Una princessa dins la Tor* (1932). Albert Pestour (1880-), also of Limousin, with a fine command of the vernacular, was the inspired poet of the *Rebuts sus l'Autura* and *L'Autura envidlada*. The very considerable number of later authors bear witness to the permanent vitality, throughout every Oc-speaking province, of Occitanian poetry.

BIBLIOGRAPHY.—*General Works:* General bibliography in D. C. Haskell, *Provençal Literature and Language* (1925), a list of references in the New York Public Library; see also P.-L. Berthaud and J. Lesoffre, *Guide des études occitanes*, 2nd ed. (1953). On the whole of Provençal literature, see C. Berthaud, *La Littérature gasconne de Bordelais* (1953). (A. A. F. B.)

PROVENCE, a historic country of western Europe, corresponding in general to the southeasternmost part of modern France from the Mediterranean coast northward over the départements of Bouches-du-Rhône, Var, Alpes-Maritimes, Basses-Alpes, and Vaucluse (*q.v.*), with the lower Rhône as its western boundary and the Alps as its eastern (though in the early Middle Ages it was sometimes understood to extend farther northward and westward). In the last centuries of the *ancien régime*, however, the French *gouvernement* of Provence, which was bounded west by Languedoc and Avignon, northwest by the Comtat-Venaissin (with three exclaves beyond it), north by Dauphiné, and east by Savoyard territory included only a fraction of the area described above, since half of the modern Vaucluse and two-thirds of Alpes-Maritimes did not belong to it.

Greeks and Romans.—Inhabited in prehistoric times by Ligurians, the Mediterranean coast was colonized, about the start of the 6th century B.C., by Ionian Greeks from Phocaea, who made their principal settlement at Massilia (Marseilles) and also founded Antipolis (Antibes) and Nikaia (Nice), as well as places west of the Rhône delta. The colonies flourished as commercial centres and as bases for exploration and did much to civilize the Celts, whose encroachment on the hinterland started in the 4th century B.C.

Early allied with the Romans, the Massiliots appealed to them for help against a coalition of Celts and Ligurians in 125 B.C. The Romans, who founded Aquae Sextiae (Aix-en-Provence), defeated the coalition and remained in occupation of the conquered hinterland as well as of country west of the Rhône, thus establishing the first Roman province in Gallia Transalpina (see GAUL)—the *provincia* whence Provence derives its name. Territory subsequently assigned to the Massiliots was taken back by the Romans in 49 B.C., since Massilia had sided with Pompey against Julius Caesar; and c. 27 B.C. a single province, Gallia Narbonensis, was constituted, to embrace coast and hinterland from the Alps to the

eastern Pyrenees. The Alpine zone, however, became a separate province, Alpes Maritimae, c. 14 B.C.

About A.D. 300 the country between the Rhône and Alpes Maritimae was made part of a new province, Viennensis, with Vienne as capital; and in 381 another province, Narbonensis II, with Aquae Sextiae as capital, was carved out between Viennensis and Alpes Maritimae. In the 390s Arelate (Arles), already the area's foremost city commercially and a Christian bishopric, became the seat of the prefecture of all the Gauls.

Goths, Burgundians, and Merovingian Franks.—On the collapse of the Western Roman Empire in 476, the Visigoths (see GOTHS), who had been intermittently attacking Arles from the west for the past 50 years, overran all Provence south of the lower Durance River, while the Burgundians (see BURGUNDY) moved into the north. After their defeat in 507 by the Franks (*q.v.*), the Visigoths yielded their place in Provence to the Ostrogoths of Italy, who soon began to supplant the Burgundians also. The Frankish conquest of Burgundy (534) and the outbreak of war between the Ostrogoths and the Byzantines (535) led to the annexation of all Provence by the Franks (536 or 537).

In their partitions of their dominions, the Merovingians allotted northern Provence, with Arles, Toulon, and Nice, to their kingdom of Burgundy; but a strip extending from Avignon to Marseilles and thence northward and eastward to the coast south of Nice was sometimes assigned to the kings of Austrasia. For most of the Merovingian period, Provence was economically prosperous, thanks chiefly to the transit trade through Marseilles.

Feebly ruled, the country was not really integrated with France. Arab invaders from Spain, who entered Provence in 732, were well received by some localities, and Charles Martel (*q.v.*), who expelled them in 739, treated Provence almost as an enemy country.

The Carolingians and the Kingdoms of Provence.—Pepin the Short and Charlemagne (*qq.v.*) made Frankish rule effective in Provence, but Arab raids began again in 813. By the Treaty of Verdun (843), between Charlemagne's grandsons, Provence went to the emperor Lothair I as part of the "Middle Realm," which stretched from the Netherlands to central Italy; but on Lothair I's death (855) his third son, Charles, received Provence (with the Viennois) as a separate kingdom. When this Charles died (863) his elder brother, the emperor Louis II, ruler of Italy, took Provence despite the designs of his brother Lothair of Lotharingia and of his uncles Louis the German and the West Frankish king Charles II the Bald (*qq.v.*). Charles the Bald acquired Provence on Louis II's death (875), but died in 877.

In 879 Boso, ruler of the Viennois, brother of Charles the Bald's widow and husband of the emperor Louis II's daughter, was elected king of Burgundy by an assembly at Mantaille. Boso's kingdom, known as that of Lower Burgundy or of Provence (see again BURGUNDY), lost territory in the north to the French and German Carolingians before his death (887); but his son Louis was elected king of Provence at Valence in 890. His kingdom included the later Dauphiné (*q.v.*) and also the Vivarais west of the Rhône.

Louis was crowned king of Italy in 900 and emperor, as Louis III (*q.v.*), in 901, but was overthrown and blinded by his rival in Italy in 905. Hugh of Arles, with the title of duke of Provence from 911 or 912, ruled for Louis till the latter's death (928), by which time Hugh had made himself king of Italy (926). Though he acknowledged Rudolf II of Burgundy as king of Provence in 934, Hugh continued in power *de facto* till his death in 947. Sovereignty over Burgundy-Provence, later known as the Kingdom of Arles (*q.v.*), was transferred by Rudolf II's grandson Rudolf III to the German king Conrad II in 1032. This sovereignty, however, was more theoretical than real.

The Countship-Marquisate.—The task of repelling the Arabs, whose raids penetrated deeper and deeper during the 9th-10th centuries, fell to the local magnates. Boso, count of Arles in 949 (d. c. 965), had two sons, Rotbald, count of Arles (d. between 1008 and 1015), and William, count of Avignon (d. 993 or 994). The latter, who appears as count of Provence in 972 and as marquis of Provence in 979, won a decisive victory over the Arabs in 983. Subsequently his male heirs and Rotbald's alike were styled count or marquis, on a basis, eventually, of joint or undivided succes-

sion, though the several lines exercised their authority from different seats—at first of course from Arles on the one hand and from Avignon on the other. By 1040, however, Rotbald's male line was extinct, while his heiress Emma was married into the house of Toulouse; and there are grounds for supposing that the Comtat-Venaissin (*q.v.*) came into being as her sons' share of the Provençal inheritance. On the death (1093 or 1094) of Bertrand of Arles, count-marquis from c. 1065, Boso's house was represented only by females or by claimants through females: (1) Gerberge, Bertrand's sister, heiress of the Arles line; (2) Alix, heiress of the Avignon line and, by marriage, countess of Urgel; and (3) Emma's grandson, Raymond IV (*q.v.*) of Toulouse.

Catalans and Toulousains.—The countship-marquisate of Provence then underwent a series of partitions. In the first decade of the 12th century the countship of Forcalquier was carved out of the northeast for Alix and her heirs to satisfy their claims against Gerberge. Then Gerberge in 1112 transferred her own rights to her elder daughter Douce or Dulce on the latter's marriage to the Catalan Ramón Berenguer III, count of Barcelona (*see* BARCELONA, COUNTS OF); and he in 1113 became count-marquis of Provence as Raymond Berengar I, since Douce transferred these rights to him. Raymond Berengar's title, however, was still contested by the house of Toulouse and soon also by that of Les Baux (*q.v.*; and *see* ORANGE, HOUSE OF), after Raymond des Baux (d. 1150) had married Douce's younger sister Stephanie. The famous treaty of Sept. 16, 1125, between Raymond Berengar I and Alphonse Jourdain, count of Toulouse (son of Raymond IV), established a frontier on the Durance: Raymond Berengar was to have the country to the south of that river, henceforward specifically called the countship of Provence; Alphonse Jourdain was to have the north, henceforward called the marquisate, as well as the Provençal dependencies west of the Rhône; but Avignon, Sorgues, Caumont, and Le Thor were to remain joint possessions of the two dynasties.

The house of Les Baux fought on for decades against the house of Barcelona; the German kings recognized one claimant after another as their vassal for Provence; and the demarcation between the marquisate and Forcalquier was not settled till c. 1174.

Raymond Berengar I died in 1131, leaving Provence to his second son Berengar Raymond (d. 1144) and Barcelona to his elder son Ramón Berenguer IV (d. 1162). The latter, however, is reckoned as Raymond Berengar II of Provence, also known as the Old, because of his long regency for his nephew Raymond Berengar III the Young. When Raymond Berengar the Young died sonless (1166), Ramón Berenguer IV's son Alfonso II, king of Aragon, took control of the countship of Provence as Alfonso I. Raymond V of Toulouse, marquis of Provence from 1148, then challenged Alfonso, but renounced his claims on the countship in 1176. Alfonso entrusted the government to his brothers Raymond Berengar (sometimes numbered as IV; assassinated 1181) and Sancho (deposed 1185, after renewed warfare with Raymond of Toulouse) and finally to his second son, Alfonso. Married in 1193 to Garsinde, prospective heiress of Forcalquier, this last-named prince became count of Provence as Alfonso II on his father's death (1196), but died in 1209.

An important feature of the 12th century had been the rise of communal regimes, under consular government, in numerous towns of Provence (*see* COMMUNE [MEDIEVAL]). Arles, Avignon, Nice, Tarascon, Grasse, and Marseilles all came to enjoy this system, usually with the support of the Church and of the local nobility, who clearly profited from the municipality's practical independence with regard to the greater feudatories. These developments coincided with a great revival of commerce. The Arab threat to the ports had practically vanished; the Crusades had opened up the Levant; and fairs in the towns inland enhanced local prosperity.

The union of Forcalquier with Provence, momentarily realized in 1208, was promptly contested by rival heirs. Alfonso II's infant son and successor Raymond Berengar IV (V if his great-uncle the governor is reckoned in the enumeration) was taken into wardship by his uncle Peter II (*q.v.*) of Aragon, but returned to Provence in 1217 and soon made good the annexation of Forcalquier.

Meanwhile a great French army from the north had set out in 1209 on the "Albigensian Crusade" against the heretical Cathari (*q.v.*) of Languedoc. The vicissitudes of the next 20 years affected the marquisate of Provence less disastrously than the other dominions of Counts Raymond VI and Raymond VII (*q.v.*) of Toulouse, though Avignon, in revolt against the crusaders, was besieged and subdued by Louis VIII of France in 1226. By the Treaty of Meaux, however, in 1229, Raymond VII agreed that his daughter Joan should eventually marry Alphonse (*q.v.*) of Poitiers, brother of Louis IX of France. As Raymond VII died sonless (1249), the marquisate of Provence passed to Alphonse and Joan with the rest of the Toulousain inheritance; and when they died (1271) it was taken by Philip III of France, who next ceded the Comtat-Venaissin to the Holy See, in accordance with provisions made in 1229.

For the countship, Raymond Berengar IV (V) had notable success in asserting his authority over the communes, though Marseilles did not finally acknowledge him till 1243. Consistently opposed to Raymond VII, Raymond Berengar also became involved in a dispute with his suzerain, the emperor Frederick II, as he frustrated Frederick's attempts to bring Arles under direct imperial control (1239). Peace, however, was made in 1241. Raymond Berengar died in 1245, leaving the countship to his youngest daughter Beatrice.

The First Angevin Countship of Provence.—Beatrice, whose acquisition of the whole Provençal inheritance was resented by her sisters (Margaret, queen-consort of France, Eleanor, queen-consort of England, and Sanchia, wife of Richard, earl of Cornwall), was married in 1246 to Charles of Anjou, later king of Naples and Sicily as Charles I (*q.v.*); and when she died (1267) he retained Provence for their son, the future Charles II (*q.v.*) of Naples. Before embarking on his Neapolitan-Sicilian venture Charles of Anjou engaged in a struggle against the Provençal communes, whose liberties he saw as dangerous to his authority. Arles and Avignon were subdued in 1251 and placed under a *viguer* or vicar nominated by the count, but Marseilles, which came to terms with Charles in 1252, later rebelled against him (1262).

The new dynasty's Italian preoccupations (*see* NAPLES, KINGDOM OF; SICILIAN VESPERS) had important repercussions on Provence. When Charles of Anjou died (1285), Charles II was a prisoner of the Aragonese, and this situation gave rise to the first recorded meeting of the Estates of Provence (*see* ESTATES-GENERAL) in 1286 and to a reorganization of the system of audit in 1288, from which the *chambre des comptes* (court of accounts) at Aix grew up. Charles II's later laws showed a concern for the welfare of his subjects as well as for his own authority. Commercially, the ports were more prosperous than ever; banking was growing up; and the reign of Charles II's son Robert (*q.v.*), king of Naples and count from 1309 to 1343, was notable for the emergence of *syndicats* (municipal councils) in the place of the consuls in many of the towns.

Avignon, which was attached wholly to the countship from 1291 (France losing the half-share inherited from the marquisate), became the seat of the papacy in 1309 and was sold to it in 1348 by Robert's granddaughter Joan I (*q.v.*) of Naples. Later, however, Joan's inconsequential dispositions and the attendant conflicts over the Neapolitan crown coincided first with the ravages of mercenary bands (let loose in the interruptions of the Anglo-French Hundred Years' War) and finally with the Great Schism of the papacy to plunge Provence into anarchy.

The Second Angevin Countship.—When Joan was murdered (1382), her latest nominee for her succession was Louis, duke of Anjou, brother of Charles V of France (*see* LOUIS, kings of Naples); but Aix and other towns formed a union in favour of his rival, Charles III of Naples, and Louis died in 1384. His widow Marie de Blois, regent for his son Louis II, gradually reduced Provence to obedience, but had to cede Nice and other frontier areas to Savoy (1383). Louis II instituted a *parlement* (*q.v.*) at Aix in 1415, but his son Louis III (d. 1434), who succeeded to the countship in 1417, replaced it by a *conseil éminent* (supreme council). Meanwhile the wars for Naples dragged on.

Louis III's brother and successor René I (*q.v.*) spent his last

decade in his Provençal castles and palaces (notably at Tarascon). While the Estates, with his consent, reformed the administration of justice, he promoted the economic revival of the country and of its ports and patronized the arts. By his will (1474) he bequeathed Provence, not to his grandson, René II of Lorraine, but to his younger brother's son, the comte du Maine, who succeeded him as Charles III of Provence in July 1480. With French help Charles III overcame René II's partisans, but in December 1481 he died, leaving his countship to Louis XI of France.

Union with France.—The Estates of Provence accepted Louis XI on a basis of personal union between the countship and the French crown (1482), thus intending to safeguard Provençal autonomy; and in 1487 they ratified a declaration in the same sense by Charles VIII of France, whereby the constitutional parity of countship and kingdom was expressly stated. Louis XII, however, established a *parlement* of the French type at Aix in 1501–02; and Francis I, whose wars led to invasions of Provence by the emperor Charles V's forces (1524 and 1536), issued his edict of Joinville in 1535, curtailing the freedom of the Estates, suppressing the *conseil éminent*, and strengthening control by the *parlement* over the local judiciaries—thus in fact reducing Provence more or less to the level of any other French province or *gouvernement*.

Savage repression of Vaudois or Waldensian heretics in Provence in the 1540s preceded the outbreak of the Wars of Religion in the 1560s (see FRANCE: History). Carcistes (Catholics) and Razats (Huguenots), Ligueurs and Bigarrats (Politiques), disputed the country till Marseilles submitted to Henry IV of France in 1596.

The *parlement* of Aix firmly resisted the edict of 1630 whereby the French government tried to abolish the Estates' control over taxation, and it was only under threat of armed constraint that the Estates in 1631 voted an extraordinary subsidy. After an obstreperous assembly in 1639 the Estates were no longer summoned for nearly a century and a half. The Fronde (*q.v.*) took an eccentric form in Provence, being characterized by hostilities between the *parlement* and the governor (L. E. de Valois-Angoulême, comte d'Alais) before the Sabreurs (adherents of the rebel princes) and the Canivets (royalists) opposed each other in the later stages. Though the Provençal Fronde ended in April 1653, discontent persisted in Marseilles, which rebelled (1659–60) and forfeited its remaining privileges. Subsequently, however, Marseilles and Toulon benefited through development for commercial and naval purposes. Louis XIV in 1673 established the *généralité* of Aix, under an intendant (*q.v.*), whose office was united with the premier presidency of the *parlement* from 1691.

Provence was invaded by Austrians and Savoyards in 1707 and in 1746, during the Wars of the Spanish and of the Austrian Succession. The *parlement*, dissolved in 1771, was reconstituted in 1775. When the French government was trying to solve its problems by provincial assemblies, the Estates of Provence reemerged in 1787–88 and in January 1789.

The *gouvernement* was dissolved into three *départements*, Bouches-du-Rhône, Var, and Basses-Alpes, in 1790. Vaucluse was formed in 1793, after the French annexation of the Comtat-Venaissin (1791). The countship of Nice, annexed to France in 1860, was merged with part of Var to form Alpes-Maritimes.

PROVERB. The Oxford Dictionary's definition of a proverb as "A short pithy saying in common use . . ." emphasizes that proverbs are part of the spoken language. They belong, in origin, to the same stage of racial history as ballad and folksong, and are related to the fable and riddle. Their literary counterparts are the apothegm, aphorism, maxim, epigram (*q.v.*), and gnome (see C. NOX and GNOMIC VERSE); although many proverbs show literary refinement. Thus "God tempers the wind to the shorn lamb," found in Sterne's *Sentimental Journey* (1768), is derived from Latin and was translated from French in George Herbert's *Outlandish Proverbs* (1640) as "To a close-shorn sheep God gives wind by measure."

Distribution and Comparison.—Proverbs are found all over the world, and their comparison provides insight into the effects of cultural conditions, language, and local variations on expression. Thus the biblical "An eye for an eye, a tooth for a tooth," has an equivalent among the Nandi of East Africa: "A goat's hide buys a goat's hide and a gourd a gourd." Both form part of codes of behaviour, and exemplify the proverb's use for transmission of tribal wisdom and rules of conduct. Often, the same proverb may be found in many variants. In Europe this may result from the international currency of Latin proverbs in the Middle Ages. "A bird in the hand is worth two in the bush" originated in the medieval Latin *Plus valet in manibus avis unica fronde duabus*, and is first found in English in the Harleian manuscript (c. 1470) as "Betyr ys a byrd in the hond than tweye in the wode." Later English versions are "three" (or "ten") "in the wood," and "One . . . in the net is worth 100 flying." The Rumanian version is "Better a bird in the hand than 1,000 on the house"; the Italian, "Better one in a cage than four in the arbour"; the Portuguese, "Better a sparrow in the hand than two flying"; the Spanish, "A sparrow in the hand is worth a vulture flying"; the German, "A sparrow in the hand is better than a crane on the roof"; and the Icelandic, "Better a hawk in the hand than two in flight."

Content and Style.—Attempts have been made to see in proverbs indications of national characteristics. Certain stylistic similarities are shown by proverbs from the same part of the world. Thus, Arabic and other Middle Eastern proverbs use pictorial forms of expression and hyperbole. Some Arabic proverbs are fables in miniature, or refer to fables; so do classical proverbs (e.g., Seneca's "Every cock crows [crouse = is master of] on his own dunghill"). Hyperbole is exemplified in the Egyptian "Fling him into the Nile, and he will come up with a fish in his mouth" of a lucky man. Dialogue proverbs are popular in Arabic, and in Greek, Ruthenian, Russian, and Polish. Classical proverbs are often terse (e.g., *Praemonitus, praemunitis* = "Forewarned is forearmed"). *Homo proponit, Deus disponit* (derived from the Vulgate version of Prov. 16:9) keeps its style in English and other translations: "Man proposes, God disposes."

Alliteration is found in proverbs of Germanic origin, which also show a liking for personification, as in "*Herr Pfennig geht voran*" ("Mr. Penny heads the procession"). Many languages make use of rhyme and play on words (e.g., the German "*Voll, toll*" = "A drunken man is a mad man"; and the Scots "Many a mickle makes a muckle"; i.e., "Many small things make one big thing").

Proverbs originating among the early Germanic peoples may reflect the heroic spirit. An 8th-century Saxon proverb "*Oft daedlata domae for-eldit gigistha gahwem; swyllit i ana*" ("A coward often misses glory in some high enterprise: therefore he dies alone") illustrates this. Its emergence, by way of the 15th-century "Taryng draweth peril," John Lyly's "Delays breed dangers: nothing so perilous as procrastination" (*Euphues*, 1579) and Shakespeare's "Delays have dangerous ends," as "Delays are dangerous" shows how changing thought and language affect expression.

Folk proverbs use homely imagery—pot and kettle, pig, sheep, horse, cock and hen, cow and bull, dog, the events of everyday life. Some proverbs first found in literary form have been adapted from speech. It is difficult to decide the authorship of a particular proverb. Abraham Lincoln is said to have invented the saying about not changing horses in the middle of the river, but he may only have used a proverb already current. Many biblical proverbs have classical parallels. "A soft answer turneth away wrath" was known to Aeschylus as well as to Solomon. "Physician, heal thyself" (Luke 4:23) is classical in origin, and "It is hard for thee to kick against the pricks [goad]" (Acts 26:14) is used by Aeschylus and Euripides.

Some proverbs refer to historical occasions. "When in Rome do as Rome does" translates St. Ambrose's answer to St. Augustine's mother, who asked whether, when in Milan, she should follow the Roman usage there and keep the Sabbath as a feast day, or that of her home town Tagaste, where it was a fast. Popular usage sometimes creates new proverbs from old ones. Thus some biblical proverbs have acquired new meanings: e.g., "The

love of money is the root of all evil" has become "Money is the root of all evil."

Many proverbs are legal in origin, although the laws to which they refer may be obsolete. The allusion in "Possession is nine [or eleven] points of the law" has defied explanation. Some refer to well-known legal principles. "An Englishman's house is his castle" is a reference to the principle by which a man is safe from the bailiffs if he shuts himself up in his own house and denies access.

Proverbs are of interest for their reference to old customs. "Good wine needs no bush" refers to the medieval custom of marking shops by a sign, and "If the cap fits, wear it" to the fool's cap. Proverbs also preserve words in obsolete senses: in "The exception proves the rule," "prove" = "test" (cf. "The proof of the pudding is in the eating"). They also embody superstitions. "Marry in May, repent away," for example, is recorded by Ovid as a current superstition and refers to the pagan idea that spring, the time of planting, was a critical period when certain tabus should be observed. Weatherlore and medical advice also find their way into proverbs: e.g., "Rain before seven, fine before eleven"; and the early 16th-century "Early to bed, early to rise/ Makes a man healthy, wealthy and wise."

Use of rhyme may show long history. "Who goes a-borrowing, goes a-sorrowing" has its origin in "He that fast spendyth must nede borowe; but whan he schal paye agen, then ys al the sorowe" (c. 1470). Sometimes style shows literary origin: e.g., "Faint heart ne'er won fair lady," of which a version is found in John Gower's *Confessio Amantis* (c. 1390).

Collections and Uses.—Proverbs in the biblical Book of Proverbs, traditionally associated with Solomon, include earlier compilations (see PROVERBS; WISDOM LITERATURE). Ancient Egyptian collections include the "Precepts of Ptah-hotep" (c. 2500 B.C.) and the "Teachings of Amen-em-apt" (c. 1000 B.C.). Sumerian inscriptions give grammatical rules in proverbial form. Proverbs were used in ancient China for ethical instruction, and the Vedic writings of India use them to expound philosophical ideas; and although these, like the Greek gnomes, are poetic and literary, they may embody popular sayings. Classical proverbs were collected in the 1st century A.D. In 1500, Erasmus published *Adagia*, a collection of 800 Greek and Latin proverbs. A later edition (1536) contained more than 4,000.

Early English proverb collections include the so-called *Proverbs of Alfred* (c. 1150–80), containing religious and moral precepts; and the more worldly *Proverbs of Hendyng* (c. 1250). Use of proverbs in monasteries to teach novices Latin, in schools of rhetoric, and in sermons, homilies, and didactic works made them widely known and led to their preservation in manuscripts.

The use of proverbs in literature and oratory was at its height in England in the 16th and 17th centuries. John Heywood wrote a dialogue in proverbs (1546, later enlarged) and Drayton a sonnet; and in the 16th century a speech in proverbs was made in the House of Commons. Proverbs were used as titles for plays (e.g., *All's Well That Ends Well*), illustrated in tapestries and paintings, engraved on cutlery, and, from the 16th to the 19th centuries, set as copies for schoolchildren, and for the making of samplers. In North America the best-known use of proverbs is probably in *Poor Richard's Almanac*, published annually between 1732 and 1757 by Benjamin Franklin. Many of "Poor Richard's" sayings were traditional European proverbs reworked by Franklin and given an American context when appropriate. In France proverbs gave rise to the *proverbes dramatiques*, dramatic sketches illustrating a proverb popular in the salons in the 17th and 18th centuries, which reached their height with Alfred de Musset (q.v.). In the 19th century, they were used in the novel to give a colloquial character to speech or to evoke the atmosphere of the past. The study of folklore (q.v.) led to the collection and study of proverbs, and this continued in the 20th century.

PROVERBS, a biblical book also known as PROVERBS OF SOLOMON (MISHLE SHELOMOH), following the Hebrew use of the initial word as title; and as the BOOK OF PROVERBS, corresponding to the Latin title. The book belongs to that section of the Old Testament designated as the Writings (Hagiographa) in contrast to the Law and the Prophets. It is also a part of the literary legacy of the Hebrew Wisdom movement of which King Solomon was the founder and patron; it is, indeed, very probably the oldest extant document of the Wisdom literature (see WISDOM LITERATURE). The beginnings of the book, in terms of earlier collections of proverbs that were ultimately absorbed by it, logically go back to the era of Solomon. It was probably completed in its present form in early postexilic times, perhaps in the 6th century B.C. Later books, also products of the Wisdom movement, include Job, Ecclesiastes (Qoheleth), Ecclesiasticus (Sirach), and Wisdom of Solomon. Among these books, Ecclesiasticus shows clear evidence of dependence upon Proverbs, both in form and content.

Contents and Literary History.—As a book, Proverbs is a collection of units originally independent. Thus at 10:1 there occurs the title "The proverbs of Solomon." At 25:1 a special unit is introduced as proverbs of Solomon copied by "the men of Hezekiah." Titles for shorter units occur in 30:1 and 31:1. The title at 1:1, "The proverbs of Solomon . . ." was probably placed there by the editors who combined the separate units to make a single book and must be understood as applying to the whole work rather than to any part of it. In addition to the sectional titles, changes in literary form and in subject matter help to mark off the limits of the various units. It seems possible to identify at least nine distinct sections, as follows:

1:1–9:18	discourses in praise of wisdom
10:1–22:16	proverbs of Solomon
22:17–24:22	30 sayings
24:23–34	supplement to the 30 sayings
25:1–29:27	Hezekian collection
30:1–14	words of Agur
30:15–33	numerical sayings
31:1–9	instruction of Lemuel
31:10–31	acrostic on the virtuous wife

Discourses in Praise of Wisdom.—The title for this section is given in 1:2–6 as a detailed statement of purpose. This is followed by the motto in 1:7, "The fear of the Lord is the beginning of knowledge," which is a leitmotiv for the entire section. It is the view of virtually all critical analysts of Proverbs that these chapters constitute the youngest unit in the book. This judgment rests on two lines of evidence.

In the first place, the literary form is complex. The independent couplet with its parallel meanings, which is the primary form for proverbs (see below), is seldom presented for its own sake, as is the case throughout in 10:1–22:16. For example, the proverb in 1:8, rather than speaking for itself, becomes the occasion for an explanation (v. 9) and an exhortation (vv. 10–19). Paragraphs such as 5:1–6 and 7:1–5 also show how the proverb is being used and absorbed in these chapters by other literary forms.

In the second place, the first nine chapters have a more

speculative quality than the remainder of the book has. The personification of wisdom (1:22 ff.; 7:1 ff.; 9:1-6) is a feature of this section almost without parallel elsewhere (cf. 14:1). Furthermore, unlike the rest of the book, these chapters do not treat wisdom simply as a human quality and achievement or as a cultural legacy imparted by teachers and parents; they present it as a universal and abiding reality, transcending the human scene. Wisdom is the first of God's works and participated with him in the creation of the world (8:22-31).

A constantly debated aspect of this section concerns the identity of "the loose [strange] woman" (2:16-19; 5:1-23; 7:1-27; cf. 9:13-18). Is the author's aim primarily ethical, or is it ideological? Is the evil woman to be taken literally as a social problem threatening the progress and integrity of the young sage? Or is she the symbol of an alien cult or of a wrong view of life? In favour of the former view such passages as 5:15-20 may be cited; and in favour of the latter, the point may be urged that just as Wisdom, the good woman, is the voice and agent of the divine intelligence, so the evil woman is the voice and agent of the satanic powers.

Proverbs of Solomon.—The Hebrew word for proverb, *masal*, means "comparison" or "parable." The primary form of this "word of the wise" was a parallelistic couplet. This section of Proverbs consists entirely of such two-line units in parallel relation to each other. Each unit is complete in itself and there is rarely a logical continuity of thought holding successive units together. In ch. 10-15 the parallelism of the couplets is overwhelmingly of the antithetic variety in which, in English, the members are held together by the conjunction "but." Thereafter those parallels in which the second line either supplements the first (e.g., 18:7) or is wholly synonymous with it (e.g., 16:16) are more prominent. The motivation of this section, in contrast to the preceding, is strongly practical: wisdom is a human achievement by means of which man's life can be fulfilled. The wise are contrasted with fools and the righteous with the wicked. But it is difficult to establish the nature of the difference, if any, between the wicked and the fool or between the wise and the righteous.

The 30 Sayings.—This section differs from the preceding most obviously by the fact that it consists of longer units or "sayings." These are introduced by a preface (22:17-21) somewhat similar to the title of the first section of Proverbs (1:2-6). The Wisdom movement in Israel was closely related to similar developments in surrounding countries (I Kings 4:29-34). Egyptian sages were especially prolific and the wisdom of Egypt had a continuous history that antedated the rule of King Solomon by at least a millennium and a half. In its outlook on life, in the subjects it treats, and in its literary forms Israel's wisdom corresponds closely to that of Egypt. This section offers most striking illustration of this, for its author used a piece of Egyptian Wisdom writing, "The Instruction of Amen-em-opet," both as a model and as a source. The "thirty sayings" (22:20) of the Israelite work represent an imitation in form of the Egyptian, which consists of 30 "chapters." The Hebrew work can be described as an anthology. The author used "The Instruction of Amen-em-opet" as one of his sources, paraphrasing parts of it. His close dependence upon it extends from 22:17 to 23:11. Thereafter, he may have utilized other sources or done his own composing.

Supplement to the 30 Sayings.—This brief section consists of four "sayings" whose tone and form show that they were intended to continue the wisdom of the preceding 30. Verse 23 emphasizes that they are a supplement to those. Verses 30-34 are a reminder that the Wisdom movement produced the parable, which becomes so prominent in the New Testament. (*Masal* means both "proverb" and "parable.")

Hezekiah Collection.—The spirit and form of this section most closely resemble 10:1-22:16. The main differences are that here quatrains as well as couplets appear and that the antithetic parallelism, so prominent in ch. 10-15, is rare. The superscription in 25:1 serves as a reminder that the polishing of proverbs, both in oral and written form, was a major interest of the movement that produced the Book of Proverbs. In Egypt the education of the young courtiers included the copying of the maxims of the sages.

The Words of Agur.—In spirit and substance this little section differs sharply from the rest of Proverbs; it has much closer affinities with the Book of Job. There is no internal evidence, such as a continuous theme, showing that these 14 verses are a single unit; but in the Septuagint they stand together between the 30 sayings and the supplement. The form is oracular, similar to the oracles of Balaam (cf. Num. 24:3 ff., 15 ff.).

Numerical Sayings.—Verses 17, 20, and 32 ff. are alien to the prominent parts of this brief section. The numerical saying has close affinities with the riddle and is common in the Wisdom materials of the ancient Near East.

The Instruction of Lemuel.—Lemuel may be thought of as a tribal chieftain of northwest Arabia, in the region of Edom. The section illustrates the role of the ruler's mother in the society of the biblical world.

An Acrostic on the Virtuous Wife.—In Hebrew this is a poem of 22 lines, each line beginning with a successive letter of the alphabet. The poem ascribes the characteristic virtues of the sages to the wife in her role as "home economist."

Character and Themes.—The Wisdom movement constitutes a very special aspect of the religious and cultural development in ancient Israel. As the primary document of the movement, Proverbs bears a clear impress of this distinctive character, so that in many respects it presents a sharp contrast to the outlook and emphases of Israel's faith as attested in the Hebrew Scriptures generally. This contrast also marks Job and Ecclesiastes, however greatly they may differ from Proverbs in other respects.

Proverbs never refers to Israel's history. In the Old Testament as a whole this history is constantly recalled not so much for social or political reasons as to declare the faith of Israel that in it God had acted to redeem his people and make known to them the character of his rule. The great themes of the promise to the patriarchs, the deliverance from slavery, the making of the covenant at Sinai, the wilderness wandering, and the inheritance of Canaan were celebrated in Israel's worship to tell the story of God's revelation of himself and of his choice of Israel. None of this is alluded to in Proverbs. The implication seems to be that for it God's revelation of himself is given in the universal laws and patterns characteristic of nature, especially human nature, rather than in a special series of historical events. That is, the revelation of God is in the order of creation rather than in the order of redemption. Moreover, the meaning of this revelation is not immediately self-evident but must be discovered by men. This discovery is an educational discipline that trusts human reason, employs research, classifying and interpreting the results and bequeathing them as a legacy to future generations. The wise are those who systematically dedicate themselves to this discovery of the "way" of God.

Unlike Job and Ecclesiastes, Proverbs is optimistic in the sense that it assumes that wisdom is attainable by those who seek and follow it. That is, man can discover enough about the character of God and his law to ensure the fulfillment of his personal life. This character of God is conceived almost entirely in terms of ethical laws. And the rewards for their observance are defined in terms of human values; e.g., health, long life, respect, possessions, security, and self-control. In this respect, the book has affinities with Deuteronomy, though differing with it in respect to the locus and form of God's revelation.

Since God is apprehended in static terms, rather than dynamically as elsewhere in the Bible, the viewpoint of Proverbs is anthropocentric. Man's destiny depends upon his responsible action. There is no appeal to divine mercy, intervention, or forgiveness; and the divine judgment is simply the inexorable operation of the orders of life as God has established them. Implicit in the book is an aristocratic bias. The wise constitute an elite nurtured by inheritance, training, and self-discipline; fools are those who can never catch up, whether because of the determinism of birth or the wasted years of neglect. In its social and cultural attitudes, the book is probably the most conservative in the Bible: wealth and status are most important; obedience to the king and all authorities is inculcated; industry and diligence are fostered, for hunger, poverty, and slavery are the fate of the lazy;

and age and accepted conventions are accorded great respect.

PROVIDENCE, the capital of Rhode Island, U.S., is located at the head of Narragansett bay on the Providence river, about 43 mi. S.W. of Boston and 180 mi. N.E. of New York city. It is an active seaport as well as an important industrial and commercial centre.

Providence is built on three hills. College hill, on which Brown university is located, rises most sharply to the east of the central business district; it was at the foot of this rise and on its slope that the first houses and shops were built. The total land area of the city is only 17.9 sq.mi. and the density of population is high (1,159 in 1960). Most of the city is closely built-up with many sections where multiple-dwellings are common. The population remained about 250,000 from 1930 to 1950, declining sharply to 207,498 in 1960. (For comparative population figures see table in RHODE ISLAND: *Population*.) In the Providence-Pawtucket standard metropolitan statistical area (SMSA) the population increased 9.3% from 1940 to 1950 and 7.4% from 1950 to 1960, its 1960 population being 821,101. The Rhode Island part of the SMSA consists of six cities (Central Falls, Cranston, East Providence, Pawtucket, Providence, Woonsocket) and seven towns (Burrillville, Cumberland, Johnston, Lincoln, North Providence, North Smithfield, Smithfield) in Providence county; two towns (Narragansett, North Kingstown) in Washington county; one city (Warwick) and three towns (Coventry, East Greenwich, West Warwick) in Kent county; three towns (Barrington, Bristol, Warrentown) in Bristol county; and one town (Jamestown) in Newport county. The Massachusetts part of the SMSA consists of one city (Attleboro) and three towns (North Attleboro, Seekonk and Rehoboth) in Bristol county; four towns (Bellingham, Franklin, Plainville, Wrentham) in Norfolk county; and two towns (Blackstone, Millville) in Worcester county. Important manufacturing centres, in addition to Providence, include Pawtucket, Central Falls, Cranston, Bristol, Woonsocket and East Providence.

Among these communities only Woonsocket and Pawtucket have well-developed separate business centres and all are dependent on Providence for many services, retail, wholesale and financial. Local bus lines operate to most of the suburbs and a network of major highways centres on Providence from all directions. Besides the English and the Irish, the major ethnic groups represented are the Italians, followed by Canadians (both English- and French-speaking) and Russians.

History.—After his banishment from Plymouth colony for his unorthodox religious beliefs, Roger Williams made his way slowly to the banks of the Seekonk river and thence by canoe to a point at the foot of what is now known as College hill, where he and his five dissenter companions found a spring with abundant water. On the way he is said to have been hailed by a friendly Indian with the words, "What cheer?"—perpetuated in the names of several businesses. From the Narragansett chieftains Canonicus and Miantonomi, Williams secured a grant of land which he named in gratitude for "God's merciful providence" and which he dedicated as "a shelter for persons distressed for conscience."

The site was a favourable one and the promised freedom of conscience appealed to many. By 1675 about 1,000 persons made up the population. Further growth was only momentarily halted by King Philip's War when 29 homes were burned by the Indians. More important in the long run was the erection of the city's first wharf in 1680 by Pardon Tillinghast; in the years which followed Providence developed into a major commercial centre. Its sailing ships to the West Indies, Africa, India, China and coastal ports carried home molasses, slaves, rum and other items in exchange for colonial exports; this trade was the basis for the development of several wealthy and powerful families whose great mansions filled

with expensive furniture and art objects rose along College hill.

Providence took a leading part in the rebellion against Great Britain which led to the colonies' independence. In 1772 a British revenue vessel, the "Gaspee," was burned off Warwick while aground. In 1775 there occurred a Providence Tea Party as an attack upon the idea of taxation without representation. Revolutionary forts were built and manned and French troops were quartered in what is now University hall at Brown university. The city was the scene of the signing of the Rhode Island Independence act on May 4, 1776, two months in advance of the country's Declaration of Independence.

In the post-Revolutionary period, Providence's crippled trade and commerce gradually recovered. The city's prosperity was augmented by new industrial development, starting with the establishment in adjacent Pawtucket in 1790 of Samuel Slater's textile mill, the first in the U.S. The town grew in size and status during the first half of the 19th century, incorporating as a city in 1832. Several notable buildings were erected, including the Arcade, an imposing covered building of many separate shops built in 1828 and designed after an Athenian temple, and the Providence Athenaeum (1836), a private library on College hill.

In the second half of the 19th century the city's industrial activities became of prime importance, supplanting but not diminishing its commerce and trade. The first important industry in Providence was the textile industry, starting with cotton factories and later expanding to include a woolen and worsted industry. Next came the jewelry industry, beginning with the little shop in which Seril Dodge made silver shoe buckles in 1786 and expanding after 1850 into a major industry. By 1880 the state was first in the nation in jewelry manufacture; 142 of its 148 plants were in Providence.

In addition to textiles and jewelry, other industries have developed to places of importance in the city and its metropolitan area, especially the machine tool and metal, rubber and electronics industries. In the second half of the 20th century Providence continued to be of major importance as the centre of the nation's most highly industrialized state.

Historic Sites.—One of the oldest cities in the U.S., Providence contains much of historic interest. The names of many streets are reminders of its trade and commerce and its early search for religious toleration; Benefit, Benevolent, Hope, Friendship, Dubloon, India and Ship streets and many others remain. Other points of historic interest in the city include the First Baptist meetinghouse, oldest of the denomination in the U.S.; First Unitarian church, its bell the largest cast by Paul Revere; the Old State house; the present capitol; and the Rhode Island Historical society, with extensive collections on Rhode Island history. The city contains dozens of old and historic homes and public buildings, many of which are open. The Old Slater mill in adjacent Pawtucket is a museum.

Education and Cultural Activities.—Despite its emphasis on industrial activity, Providence is an educational, cultural and recreational centre. The oldest of its several colleges is Brown university, founded in Warren in 1764 as Rhode Island college (see MANNING, JAMES), moved to Providence in 1770 and renamed Brown university in 1804 in honour of Nicholas Brown, a treasurer of the college and a principal benefactor. Its women's college is Pembroke, organized in 1891.

John Hay library, erected as a memorial to John Hay, secretary of state under Presidents William McKinley and Theodore Roosevelt and a Brown graduate in the class of 1858, and other college libraries contain about 850,000 volumes and many special collections. On the campus are the John Carter Brown library, containing the world's foremost collection of Americana printed prior to 1801, and the Annmary Brown memorial, with a world-famous collection of incunabula from the period 1460 to 1500. Brown's Haffenreffer museum, located at Bristol, has a growing collection of Indian and other anthropological materials.

The Rhode Island School of Design is a private, coeducational college, founded in 1877 and providing four-year degree programs in the fine arts, architecture, design and related fields. The school's museum is notable for its collections of early furniture

and early American crafts. There are comprehensive collections of paintings and sculpture of various periods and an oriental collection.

Other institutions of higher learning in Providence include the Rhode Island college, a state college chartered in 1854 and now offering teacher training on a handsome 48-ac. campus opened in 1958; and Providence college, a liberal arts college for men, founded in 1917, Roman Catholic.

The Providence Public library facilities were approximately doubled in 1954 by the opening of a new wing to the main building, erected in 1900. There are several branch libraries and one or more libraries in each of the towns in the metropolitan area.

Recreational Facilities.—The city maintains several parks and playgrounds and a municipal golf course. The largest park is Roger Williams park, with 453 ac. of lakes, flower gardens, walks, animal and bird houses, a museum of natural history, Betsey Williams cottage and a small amusement area for children.

Several state parks and picnic grounds are located in the metropolitan area. Yacht clubs and marinas are found in several waterfront communities and sailing and other forms of boating are common on Narragansett bay and adjacent waters. A ski slope and tow are operated by the state in Cumberland in winter. Dozens of ocean resorts lie just beyond the metropolitan area on the bay and the Atlantic ocean.

(V. H. WH.)

PROVINCE, ROMAN. The Latin word *provincia* meant originally the sphere of duty assigned to a magistrate; thus civil jurisdiction between citizens was the *provincia* of the urban praetor. When magistrates were assigned the government of dependent territories, the name was applied to these territories.

The Republic.—After the First Punic War Rome acquired western Sicily and Sardinia and Corsica from Carthage. About 20 years later, in 227 B.C., two additional praetors were elected

each year to govern them. (See **PRAETOR**.) After the acquisition of the two Spains (Hispania Citerior and Hispania Ulterior) following the Second Punic War, two more praetors were added in 197 B.C. Thereafter, although new provinces were acquired (Africa, Macedonia, Asia, Gallia Narbonensis) no more praetorships were created, and the requisite number of governors was supplied by the prorogation for a year or more of the command of praetors (including the two praetors at Rome, who might serve a second year in a province *pro praetore*). When a serious war broke out in a province it was usually assigned to one of the consuls (whose command might be prorogued *pro consule*). A praetor might also be given *imperium pro consule*, if entrusted with a large army. From the time of Sulla, consuls and praetors rarely governed provinces in their year of office, which they spent at Rome, but usually took a second year *pro consule* or *pro praetore* in the provinces.

In the last years of the republic special provincial commands, sometimes of several provinces and usually for a longer term (five years), were assigned to individuals who were not the consuls or praetors of the year or the preceding year. By a *lex Pompeia* of 52 B.C. Pompey enacted that there should be a five-year interval between a magistracy at Rome and a promagistracy in a province. The provinces to be filled by the consuls and praetors were annually determined by the Senate, which also prorogued the command of the governors who were not to be relieved; the consuls and praetors either drew lots for their provinces or selected them by agreement.

The general who annexed a province laid down a basic statute (*lex provinciae*), usually with the assistance of ten commissioners (*decem legati*) appointed by the Senate. This *lex* established the system of taxation, which sometimes took the form of a fixed *stipendium* levied on each community in the province, sometimes

Roman Provincial Organization at End of 4th Century

Name of province	Date of annexation	Title of governors in the principate*	Equivalent provinces in A.D. 400	Title of governors	Diocese

Cyprus	58 B.C.; separate province from 22 B.C.	proconsul (praet.)	Cyprus	consularis	Oriens
Dacia	A.D. 107; evacuated by Aurelian c. 270 before 59 B.C.	legatus Augusti (cos.)			
Dalmatia Egypt see Aegyptus Epirus	146 B.C. (with Macedonia); separate province from Hadrian or Antoninus Pius	legatus Augusti (cos.) procurator	Dalmatia Praevalitana Epirus Vetus	praeses praeses praeses	Pannonia Dacia Macedonia

assisted by one or more *legati*, appointed by the Senate on his nomination; to them he could delegate military commands or jurisdiction. He chose a *praefectus fabrum* and other *praefecti* and *tribuni*, to whom he could assign lesser military commands or judicial or administrative duties. (See PREFECT [PRAEFECTUS].) He was also accompanied by unofficial assistants (*comites*). He was served by an official secretary (*scriba*) and other staff (*apparitores*) including lictors (*q.v.*).

The evidence is overwhelming that the provinces were on the whole badly treated under the republic. The governor, exercising irresponsible power, extorted money from the provincials by a variety of means: judicial corruption, misuse of his rights of requisition, and sundry forms of blackmail. His staff also expected their share of the pickings. Where the taxes were collected by *publicani* they too expected to make additional profits by overassessment of the tax due, and Roman financiers (*negotiores*) profited from the financial straits of the provincials by lending them money at fantastic rates of interest. Provincial extortion is first heard of in 171 B.C. when the Spaniards petitioned the Senate. In 149 B.C. a special court was established at Rome to deal with extortion (*de rebus repetundis*). The jurors in this court were at first senators, who regarded their colleagues' misdeeds with sympathy. From 122 B.C. they were *equites*, who used their power to protect the interests of the *publicani*, who were members of this order.

The Principate.—In 27 B.C. Augustus was assigned a group of provinces, and henceforth the provinces of the empire were divided into "imperial" (*provinciae Caesaris*) and "senatorial" (*provinciae publicae*). The latter, which were ungarrisoned (save for Africa and Macedonia at first), were governed, as under the late republic (under the *lex Pompeia*), by former consuls and praetors, who were all styled proconsuls, on an annual term. Their number was never increased after 23 B.C. The imperial provinces greatly increased in extent, for all newly annexed areas went to the emperor. They were mostly governed by senators, appointed by the emperor (*legati Augusti pro praetore*), who served during his pleasure; three years became the normal term. Provinces with one legion or none had a legate of praetorian rank, those with two or more legions one of consular rank, who was assisted by the legates of the legions and in some cases by a judicial legate (*legatus iudicis*). Egypt with its three legions (later reduced to two and then to one) was by exception governed by an equestrian prefect, with equestrian prefects of the legions and other equestrian judicial and financial assistants. A number of minor provinces, either turbulent areas like the Alpine districts or annexed kingdoms like Judaea, were governed by equestrian officers known at first as *praefecti*, but from the time of Claudius generally as procurators. In all provinces except those governed by prefects and procurators there was a *procurator Augusti*; in the senatorial provinces he was concerned only with the emperor's private estates, but in the imperial provinces he collected the revenues and paid the troops. The old staff of *apparitores* survived but was increasingly superseded by military clerks; procurators were also served by imperial slaves and freedmen.

Although oppression and extortion were by no means eliminated, in general the condition of the provinces was greatly improved under the principate. In the imperial provinces the governors were selected by the emperor, and in the senatorial he could intervene in virtue of his *imperium maius*. Cases of extortion now came before the Senate, where the emperor could sway the verdict, and appeals to the emperor from the judgments of governors were encouraged. The diet of the province (*concilium provinciae*) came to play an important part in protecting the interests of the provincials. Such diets, consisting of delegates from the several communities, had existed in some provinces under the republic. Under the principate they became universal, and besides celebrating the worship of Rome and Augustus, they passed votes of thanks to popular governors and conducted prosecutions of those who were oppressive or extortionate. They also could make petitions to the emperor and send delegations to him to plead their interests. Provincial taxation was also reformed. For the tithe was substituted a poll tax (*tributum capitis*) and land tax (*tributum soli*)

assessed on the basis of periodic censuses; the *publicani* were eliminated (save for indirect taxes) and the tribute was collected by the provincial communities. Finally the status of the provincials was improved by the grant of Latin right (see LATIN RIGHTS) and Roman citizenship in the West, where an increasing number of communities, sometimes whole provinces, such as Spain under Vespasian, were given Latin status, and a large number were made *municipia* or *coloniae civium Romanorum*. In the Greek-speaking provinces of the East, Latin status was not accorded and only a few cities became Roman colonies. All these distinctions were obliterated when, by the Constitutio Antoniniana of A.D. 212, all the inhabitants of the cities became Roman citizens.

Under the principate there were a few provinces which were not groups of self-governing communities but were directly administered on bureaucratic lines. The leading case was Egypt, where the Ptolemaic administrative system was preserved with little change; in some smaller annexed kingdoms, such as Judaea and Cappadocia, a similar system prevailed. The Roman government, however, preferred indirect rule, and Septimius Severus established councils in the capital towns of the *nomes* (administrative districts) of Egypt and gave them some degree of administrative responsibility.

Diocletian (*q.v.*) approximately doubled the number of provinces, bisecting many and splitting some into four or five; he also divided Italy into provinces. He grouped the provinces into 13 larger circumscriptions called dioceses and governed by *vicarii* of the praetorian prefects. He preserved the proconsuls of Africa and Asia and placed Sicily and the Italian provinces under *correctores* who were usually senators, but elsewhere appointed only equestrian governors, styled *praesides*. Constantine and his successors increased the number of dioceses to 15 and raised the rank of many governors to *consularis*, thus making them senators.

(A. H. M. J.)

PROVINCETOWN, a town of Massachusetts, U.S., situated among extensive sand dunes within a fishhook-shaped harbour at the northern end of Cape Cod, is a noted artists' colony, fishing port and tourist centre. Discovered by explorers Bartholomew Gosnold and Henry Hudson in 1602 and 1609, it was the first landing place of the Pilgrims before they founded Plymouth. The birth of Peregrine White, the first white person born in New England, and the signing of the Mayflower Compact both occurred on shipboard in Provincetown harbour. Settled by lawless traders and fishermen before 1700 on lands owned by the Province of Massachusetts Bay (hence its name), the village was first a precinct of the town of Truro and in 1727 became a separate township. Its exposed position, subject to repeated attacks by sea, forced its abandonment during the French wars and the American Revolution. Its magnificent harbour was used as a naval base by British blockading squadrons in the Revolution and the War of 1812. In the 19th century it was an active maritime and whaling port, and its Portuguese descendants still maintain there the most prosperous fishing industry on Cape Cod. Until 1900 its communications with the mainland were mostly by boat because of the wind-blown loose sand that swept across its highways.

Modern Provincetown was for some time the home of Eugene O'Neill, whose first produced play, *Bound East for Cardiff*, was staged there in 1916 by the Provincetown Players. The top of the great Pilgrim monument, 350 ft. above the sea, affords a superb view of the cape and Massachusetts bay. Drives along the sand dunes, buried forests and shipwreck-littered beaches are popular with tourists. The close-packed streets and wharves of the old maritime town are annually explored by thousands of visitors. The resident population is about 3,500. (H. F. Ho.)

PROVINCETOWN PLAYERS, an experimental theatrical group, was organized in 1915 at Provincetown, an artists' colony in Massachusetts. Its program, the creation of a vital American drama, derived philosophical support from the hypotheses of Jane Ellen Harrison and Gilbert Murray (*qq.v.*). In 1916 they staged *Bound East for Cardiff*, the first of Eugene O'Neill's plays to be produced. That winter they moved to New York's Greenwich Village where, calling themselves the Playwrights' theatre, they encouraged playwrights, actors and stage

technicians to "work out their ideas in freedom." The result was to provide an impetus to the individual artists and playwrights (particularly O'Neill), who were responsible for the renaissance of the American theatre after 1920, and to demonstrate to the commercial theatre that its patrons were as ready for provocative treatment of contemporary themes as patrons of museums or novel readers. The group disbanded in 1929. (A. S. Dr.)

PROVING GROUND, an area set aside and usually specially modified and equipped to "proof test" military devices and military and commercial vehicles. The purpose of such testing is to show up, by excessive or distorted operation, the weaknesses of an item or any of its components; to determine whether the item's operation fits into a standard pattern; or to determine the life expectancy of any product. In many instances, items are tested to destruction; in the case of ammunition the test is actually an expenditure of sample quantities from each lot made. In all cases, data are collected, evaluated, and used in further development or in making engineering or production improvements.

Vehicle proving grounds, whether military or commercial, have a wide variety of roads and road surfaces to cause the vehicle under test to be strained or overworked in one manner or another. Corduroy tracks twist the car frame to determine its stamina; steep slopes show whether the engine can develop sustained power under unusual demand; braking power is tested when a stop is made on the slope. Tires are tested on many types of cobbles and broken stones and in sand and deep mud. Engines and brakes are proof tested by running the vehicle through deep water; brakes and tire traction are put to further test by passing through deep mud.

Military proving grounds also have special facilities and instruments for proofing guns of all sizes, from small arms to the largest cannon. Rifles or machine guns may be fired from stands in indoor ranges to test the gun barrel's resistance to wear when fired at excessive rates, to determine its ability to operate at extreme ranges of temperature or in dust or rain, or to allow studies of bullet flight by flash photography. Some artillery weapons are also fired indoors, but more often the firing is in the open against various types of targets, including different thicknesses of armour plate. Prominent on the artillery test range are tall towers supporting large metal rings. These rings are solenoids (electrical coils affected magnetically by the presence of moving steel objects) through which shells are fired to study their behaviour.

Proving grounds for rockets and guided missiles are distinctive primarily because of the much greater ranges involved. They are usually located in sparsely settled areas where missiles may be fired distances of 100 mi. or more; sometimes they are on coasts so that firing may be out to sea.

Notable proving grounds in the United States are several commercial vehicle test areas maintained by manufacturers of motor vehicles near Detroit, Mich.; the U.S. Army's Aberdeen Proving Ground near Baltimore, Md., for guns, ammunition, and combat and transport vehicles; and the U.S. Army's White Sands Missile Range in New Mexico for rockets and missiles. Aberdeen's area is more than 70,000 ac., but shells may be fired as far as 30 mi. out over Chesapeake Bay. White Sands is a desert valley 40 mi. wide and about 100 mi. long. Very long range missiles for the Army and the Air Force are fired southeastward into the Atlantic Ocean from Cape Kennedy (formerly Cape Canaveral), Fla., and into the Pacific Ocean from Vandenberg Air Force Base in California. These facilities are generally referred to as missile ranges rather than proving grounds.

Germany's great proving ground at Hillersleben before and during World War II resembled Aberdeen Proving Ground in that it permitted the proof testing of many types of weapons and other material at one place. The United Kingdom, however, spread the proof testing or tryout operations to different areas. For example, tanks were tested at Castle Douglas in Scotland; artillery at Holyhead, Anglesey, in Wales and at Lark Hill, Wiltshire, in England; infantry weapons and ammunition at the small arms school at Hythe, Kent, in England. Long-range rockets and missiles developed within the British Commonwealth are tested at the Woomera Range in Australia. (F. D. McH.)

PROVINS, a town of north-central France, *département* of Seine-et-Marne, lies on the Durteint and Voulzie streams, 52 mi. (83 km.) ESE of Paris by road. Pop. (1962) 7,243. The old town is on a hill, with the new town in the valley below. There are many medieval houses, with narrow cobbled streets, dominated by the Tour de César (the 12th-century castle keep). Churches include St. Quiriace (12th–13th centuries), St. Ayoul (12th–16th), the bell tower of the convent of Notre Dame, and St. Croix (13th–16th). The old town is partly surrounded by medieval ramparts with gateways and towers. Other buildings of interest include the Grange aux Dimes, a tithe barn (13th century); the Hôtel-Dieu (former palace of the countesses of Blois and Champagne, now a hospital); and the college, on the site of the counts' palace. Provins is on the railway from Esternay to Longueville, both linked with Paris. It lies in the heart of a wheat and sugar-beet region and has important clay pits.

Provins is said to have been named Probinum after the Roman general Probus who was there in A.D. 271. The lower town was founded in the 9th century by religious refugees fleeing from the Normans; they brought with them the remains of the martyr St. Ayoul, and the town became a place of pilgrimage. At this time it belonged to the counts of Vermandois; later it was the residence of the counts of Champagne, under whom it became a prosperous wool centre, with 80,000 inhabitants in the 13th century, and its fairs were attended by merchants from all over Europe (see CHAMPAGNE). After the death of Henry III of Champagne in 1274 its prosperity declined. The name "city of roses" was given to Provins because of its cultivation of the red rose imported from the East by the crusader Thibaut IV of Champagne (d. 1253). Edmund of Lancaster, whose descendants had the red rose as their badge (see ROSES, WARS OF THE), married Count Henry III's widow in 1275 and governed Champagne until 1284. (A. G. St.)

PROVISION, in ecclesiastical law, signifies the conferring of an office or benefice. With King John's submission to the pope in 1213, presentations of this sort previously made by English patrons were gradually appropriated by Rome to finance the increasingly costly centralized church administration. To secure papal aid in international affairs, English kings tolerated this system, resented by Commons because so many foreigners were granted English benefices by the pope, until the coincidence of the Hundred Years' War with France and the Avignon papacy led to the enactment of the Statutes of Provisors (1351) and of Praemunire (1353) which outlawed the practice. Nevertheless, despite this and subsequent legislation, papal provision continued, abetted by the king, who eventually managed to secure virtual control over the pope's nominations. Provision was finally eliminated with the death of Mary Tudor. Though papal provision was legally sound, its abuses, condemned alike by satirists and saints, provoked such mass indifference toward the church that it must be considered one of the prime causes of the 16th-century collapse of Catholicism.

PROVISIONAL ORDER: see ADMINISTRATIVE LAW.

PROVO, a city of Utah, U.S., the seat of Utah county, is situated 45 mi. S. of Salt Lake City between Utah lake and Wasatch peaks, at an altitude of 4,549 ft. An amalgam of weathered gray adobes and modern structures of frame or brick set amid trees and gardens, Provo has a dual modern identity as college town and steel centre.

The city takes its name from the Provo river, named for the trapper Étienne Provost (c. 1782–1850), who penetrated to Utah from New Mexico in 1824. Brigham Young sent a Mormon colonizing mission to the site in 1849 and the next year what had been Ft. Utah by legislative fiat became Provo. Incorporated in 1851, Provo was Utah's second city until the Pacific Railroad gave Ogden predominance in 1869.

Decisive in Provo's early fortunes was the founding in 1875 of

Brigham Young academy, a Mormon institution which in 1903 became Brigham Young university. After 1923, steel plants were built in northern and southern suburbs; the Geneva plant, erected during World War II, became the largest integrated steel plant in the western U.S. and Utah's largest single manufacturing enterprise. The city has some other industry and is the trading centre for a rich agricultural area. It has a council-manager form of government, in effect since 1956.

The population of Provo was 36,047 in 1960; that of the Provo-Grem standard metropolitan statistical area (Utah county) was 106,991. For comparative population figures see table in UTAH: Population. (D. L. M.)

PROVOOST, SAMUEL (1742–1815), first bishop of the Protestant Episcopal Church in New York, was born in New York city on Feb. 26, 1742. After graduating from King's college (later Columbia university) in 1758, he went to England for further study, becoming a fellow-commoner of St. Peter's college, Cambridge, in 1761. Though of Reformed background, he united with the Church of England in his college days, if not earlier. He was ordained deacon on Feb. 23, 1766, and priest on March 25, 1766. Returning to America, he was elected assistant minister of Trinity church, New York, in Dec. 1766, resigning in 1771 because of ecclesiastical and political differences with the vestry. Though strongly sympathetic to the American cause in the Revolution, he took no active part in the dispute, living in retirement on a farm in Dutchess county until the end of the war. After the British evacuated New York, the Whig party gained control of the parish of Trinity church and elected Provoost rector. He was appointed a regent of the University of the State of New York in 1784 and served as chaplain to congress in 1785. He took an active part in the organization of the Protestant Episcopal Church after the Revolution and was elected bishop of New York on June 13, 1786. With Bishop William White of Pennsylvania he was consecrated in England on Feb. 4, 1787. They were the first two Americans to be consecrated by English bishops. Provoost was elected chaplain of the U.S. senate in 1789. Ill-health compelled him to retire from all active duty in 1801. He died on Sept. 6, 1815.

(W. W. Ms.)

PROXY (short for "procuracy"), a term denoting either a person who is authorized to stand in place of another or the legal instrument by which the authority is conferred. Proxies are now principally employed for certain voting purposes. A proxy may in law be either general or special. A general proxy authorizes the person to whom it is entrusted to exercise a general discretion throughout the matter in hand, while a special proxy limits the authority to some special proposal or resolution.

In English and American bankruptcy proceedings creditors may vote by proxy, and every instrument of proxy, which may be either general or special, is issued either by the official receiver or trustee. Under the English Bankruptcy Act of 1914 and the American Bankruptcy Act of 1898, as reenacted in 1938, a creditor may still vote by proxy in the manner prescribed.

The greatest modern importance of proxies is in their use in shareholder voting. The Companies Act (1948) in England and the state statutes in the United States provide that voting by shareholders of limited liability companies and of corporations shall be in person or by proxy.

The separation of share ownership from management, in corporations in which shareholding is widely held by the public, has made the proxy a powerful control weapon, since a majority of shareholders can rarely be assembled in person for meetings at which directors are elected. Because annual shareholders' meetings are usually required by law, the management of such corporations can and normally does solicit the proxies of all shareholders at the company's expense, obtains the proxies of a quorum and majority, and votes the proxies for directors of its choice.

Lack of protection of absent shareholders led to enactment of provisions in the Securities and Exchange Act of 1934 authorizing the Securities and Exchange Commission (SEC) to issue regulations governing proxy solicitations. These regulations apply to proxies in corporations whose shares are traded on stock exchanges and to all other corporations having total assets of \$1,000,000 or

more and (after July 1, 1966) 500 or more shareholders. They require solicitations for proxies to be accompanied by statements informing the shareholder of the measures, so far as known, that will be acted upon at the meeting, and naming and giving detailed information about the directors proposed to be elected or reelected. The proxy itself must show that it is solicited by management, must give the shareholder an opportunity to instruct his proxy how to vote, and must be signed and dated.

These regulations also govern solicitation of proxies by dissident shareholders. They require that management proxy statements include, under certain circumstances, proposals for shareholder action by non-management shareholders, as well as written statements in support of such proposals. Furthermore, the rules sharply restrict the manner of garnering proxy votes by prohibiting the use of statements that have not been approved by the SEC.

These regulations have made it easier for groups of shareholders to contest management control, although in widely held corporations the cost is extremely high. When a contest takes place, the reasonable costs of solicitations, which may include the services of professional soliciting companies that telephone and visit shareholders, may lawfully be charged by successful or unsuccessful management groups, or by successful groups of dissident shareholders, to the company, but the cost to an unsuccessful dissident group falls on its financial backers. The uncertainty of the outcome of such contests is heightened because a proxy is usually revocable until actually voted at the meeting. When a shareholder gives more than one proxy, as often happens, because he is either confused or has changed his mind, only the last-dated proxy counts.

(G. T. Fr.)

PRUDENTIUS (AURELIUS PRUDENTIUS CLEMENS) (348–after 405), Latin poet who presented Christian doctrines in a form agreeable to those steeped in the old literary tradition. Born in Hispania Tarraconensis, possibly at Caesaraugusta (Saragossa), he studied rhetoric, practised at the bar, held two provincial governorships, and was elevated by the emperor Theodosius to a high, and doubtless honorary, position at court. Tiring of the vanity of life, he devoted himself from about 392 to writing poetry on Christian themes. In 405 he edited a collection of his poems with an autobiographical preface.

The *Cathemerinon liber* comprises 12 lyric poems on various times of the day and on church festivals. The symbolism of light and darkness runs through these, occasionally developing into sustained allegory. The *Peristephanon* consists of 14 lyric poems on martyrs, mainly those of his native Spain, but some were inspired by a visit to Rome in 401–403. In these poems a taste for the gruesome is wedded to a simple piety. In three long didactic poems in hexameters he gives a polemical exposition of Christian doctrine. The *Apotheosis* attacks the views on the Trinity of Patristians, Sabellians, Jews, Ebionites, and Manichaeans, and sets forth the Orthodox view. The absence of polemic against Arians and Priscillianists is probably due to caution rather than to ignorance. The *Hamartigenia* refutes dualist views on the origin of sin; though Marcion is often mentioned, Priscillian, and perhaps Pelagius, are the real targets. The *Psychomachia* describes the struggle of Faith, supported by the cardinal virtues, against Idolatry and the corresponding vices for the soul of man. The first completely allegorical poem in European literature, it enjoyed immense influence in the Middle Ages. The two *Libri contra Symmachum* were written in reply to a second request by the pagan senator Symmachus that the altar of Victory be restored to the senate house, probably in 402/403. Book i is a critique of pagan polytheism; book ii replies to Symmachus' first request (*relatio*) in 384, developing the arguments then used by Ambrose, bishop of Milan. The *Dittochaeon*, 49 hexameter quatrains, intended as captions for the mural paintings in a basilica in Rome, is of interest mainly to the art historian. In a short lyric epilogue the poet offers his gift of verse to God.

Prudentius gives classical literary form to Christian content without any element of travesty. His poems are full of echoes of Virgil, Horace, Seneca's tragedies, and Lucan. But what he has to say he owes to the Bible (which he knew in a pre-Hieronymian

but elegant version), Tertullian, Arnobius, Lactantius, Ambrose, and the Acts of the Martyrs. In vocabulary he uses many neologisms to express Christian concepts, which became part of the common stock of medieval poetry. A tasteful metrician, he not only uses hexameters, iambic trimeters, and many of the lyric metres of Horace, but freely introduces new lyric metres of his own. All the techniques of ancient rhetoric are at his command.

PRUD'HON, PIERRE PAUL (1758–1823), French artist, was a painter of uneven quality and a draftsman of genius. He was born at Cluny on April 4, 1758, the 13th child of a stonemason. He trained with François Devosge, the director of the art school at Dijon, and then, through the patronage of a local nobleman, the baron de Joursanvault, spent a few years in Paris. In 1784 he was awarded the triennial prize of the Estates of Burgundy, which enabled him to go to Rome for three years. Of his stay in Rome only a few drawings survive, together with a ceiling painting now in the museum at Dijon. It is obvious that he looked at the works of Correggio and Leonardo, and his introduction of softer, more sensual effects into a school of painting dominated by the static and sculptural style of David is his greatest claim to originality.

His early miniature manner, however, persisted for some time after his return to Paris about 1789 (in vignettes designed for stationery used in government departments and book illustrations for the publisher Didot). His manner was broadened and his reputation extended by his decorations for the Hôtel de Lanois in Paris, although these can now be judged only by his preliminary drawings and sketches. Frochot, prefect of the Seine, brought him to the attention of Napoleon, who employed him intermittently as court portraitist and court decorator. His portrait of the empress Jose-

ART REFERENCE BUREAU

DETAIL FROM THE PORTRAIT IN OIL OF EMPRESS JOSEPHINE PAINTED BY PIERRE PRUD'HON IN 1805. IN THE LOUVRE, PARIS

phine of 1805 (Louvre)—Canova crossed with Correggio—is an excellent example of his seductive mildness. Although an exceptionally lazy worker, Prud'hon painted a number of large allegories, of which the best known are "Crime Pursued by Vengeance and Justice" of 1808 (Louvre) and "Venus and Adonis" (Wallace Collection), which was exhibited in the Salon of 1812. Such pictures have now darkened badly owing to Prud'hon's imperfect understanding of the aging of pigment. His drawings, however, have retained their exceptional qualities, as can be seen in his study for

a state portrait of Marie-Louise (Louvre) or his designs for the toilet service which was the wedding present offered to her by the city of Paris. Prud'hon continued to receive government commissions even after the Restoration, and in 1816 he was made a member of the Institute. His last years were shattered by the suicide of his devoted mistress, Constance Mayer, a dramatic episode which was the direct cause of his own death in Paris on Feb. 16, 1823.

PRUNE: see **PLUM**.

PRUNING: see **ARBORICULTURE**; *Pruning*; **FRUIT FARMING**; *Basic Problems and Practices of Fruit Farming: Training and Pruning*.

PRUNUS, a highly important genus of more than 150 species comprising the well-known stone fruits of the Rosaceae family. See **ALMOND**; **APRICOT**; **CHERRY**; **NECTARINE**; **PEACH**; **PLUM**.

PRUSSIA, the name given in European history (1) to a tribal country on the southeastern coast of the Baltic Sea; (2) to the territories into which this country was divided between Germans and Poles; (3) to the kingdom which arose from the German territory under the Hohenzollern dynasty; (4) in an extended sense, to the aggregate of Hohenzollern possessions not only in the specifically Prussian country but also throughout Germany; and (5) to the Land into which the former Hohenzollern possessions were transformed under the Weimar Republic and which survived as a component of the German *Reich* till its dissolution after World War II.

ANCIENT AND MEDIEVAL PRUSSIA

The Old Prussians.—The original Prussians, in medieval sources variously called Prusi, Pruzzi, Borussi, etc., were a group of tribes inhabiting the country between the Vistula and lower Niemen (Neman; Memel) rivers. They belonged, with their Lithuanian neighbours and with the Latvians, to the Baltic family of the Indo-European peoples (see **BALTS**). The Prussians are described as living dispersed in small clusters in heavily wooded country. They were predominantly hunters, collectors of honey from apiaries, and cattle breeders, but practised some primitive agriculture with wooden tools. Their social organization was loose, but some elements of a stratified society can be traced. They were pagans, having holy groves as their sanctuaries, and adhered tenaciously to their religion.

The German kings of the Saxon dynasty made contact with eastern Europe in the 10th century A.D. (see **GERMANY: History**), but the first attempts to convert the Prussians to Christianity ended in failure. The Czech bishop Adalbert (q.v.) was killed as a missionary in Prussia in 997; and his disciple Bruno (q.v.) of Querfurt died in the same way in 1009. For the next 200 years the Prussians remained pagan in their forests.

The Teutonic Order and the Poles.—The Cistercian monk Christian of Oliva, whom Pope Innocent III consecrated as bishop in 1215, had very little success in his task of converting the Prussians. Then, in 1230, the Polish duke Conrad of Mazovia gave land to the Knights of the Teutonic Order (q.v.) for help against Prussian raids on his territory.

The Teutonic Order proceeded to subdue the country along the Baltic coast east of the lower reaches of the Vistula: it built a network of castles, settled German noble families on the conquered lands, and established markets for the control of trade. The peasant population, which under these circumstances appeared to accept Christianity, still consisted of the old Baltic stock. Those members of the indigenous upper class who would acknowledge the new overlords were recognized as landowners.

In 1261 a great rebellion of the Prussians broke out. For ten years the order's rule was in danger of annihilation; and even after this crisis had been overcome there was still violent fighting for another decade. To restore the productivity of the country the order started a systematic settlement of German peasants, who brought with them the iron plow and so could turn the heavy soil of former forests into arable land. That part of the indigenous Prussian population which the order considered loyal was allowed to keep its land and status, and the Old Prussian language did not

become wholly extinct till the 17th century; but by the middle of the 14th century the majority of the inhabitants of Prussia were German-speaking. For further details of the organization of Prussia see **TEUTONIC ORDER, KNIGHTS OF THE**.

The latter part of the 14th century was characterized in eastern Europe by a strong reaction among Slavs and Balts against the Germans. Poland and Lithuania formed their first dynastic union in 1386, and the Teutonic Knights were defeated by the Polish-Lithuanian forces in the Battle of Grunwald (*q.v.*), or Tannenberg, in 1410. By the first Peace of Torun (Thorn), in 1411, the Dobryzn area, on the right bank of the Vistula above Torun, into which the order had infiltrated, was surrendered to Poland; and after renewed warfare the second Peace of Torun was signed in 1466. By this treaty the Polish crown acquired direct sovereignty over the order's former possessions to the west of the lower Vistula, together with the Kulmerland (or Chelmno district) and Ermland (Warmia) to the east; and the eastern part of Prussia was left to the order only on condition that the grand, or high, master should hold it as a fief of the Polish crown. See also **EAST PRUSSIA**.

THE 16TH AND 17TH CENTURIES

Polish Royal Prussia.—The lands on the Vistula, under Polish sovereignty, became known as Royal Prussia. The westernmost area, Pomerelia, in fact the eastern part of Pomorze (*q.v.*), had not come under the order's control till the 14th century and so was less germanized than the country east of the Vistula, to which most of the German peasant colonists were directed. The provincial constitution which was granted to Royal Prussia in 1571 strengthened the link between the local nobility and the Polish. Thus a wedge of predominantly Polish-speaking territory was consolidated between German-speaking East Prussia and the German *Reich*.

Ducal Prussia and Brandenburg.—The Teutonic Order's last grand master in Prussia, Albert (*q.v.*) of Hohenzollern, became a Lutheran and, in 1525, secularized his fief, which he transformed into a duchy for himself. Thenceforward till 1701 this territory was known as Ducal Prussia. When Albert's son and successor Albert Frederick died sonless in 1618, the duchy passed to his eldest daughter's husband, the Hohenzollern elector of Brandenburg, John Sigismund (see **HOHENZOLLERN**: Table III).

The union of Ducal Prussia with Brandenburg (*q.v.*) was fundamental to the rise of the Hohenzollern monarchy to the rank of a great power in Europe. John Sigismund's grandson, Frederick William (*q.v.*) of Brandenburg, "the Great Elector," by military intervention in the Swedish-Polish War of 1655–60 and by diplomacy obtained the ending of Poland's suzerainty over Ducal Prussia at the Peace of Oliva (1660). This made the Hohenzollerns sovereign over Ducal Prussia, whereas Brandenburg and their other German territories were still nominally parts of the *Reich* under the theoretical suzerainty of the Holy Roman emperor. Frederick William was also able to set up a centralized administration in Prussia and to secure control of the duchy's financial resources, thus reducing the power of the Prussian *Landstände* or Estates (see **ESTATES-GENERAL**). These Estates, comprising the landowning nobility and the oligarchies of the towns, among which Königsberg was paramount, had previously run the duchy's affairs. (H. Lz.)

THE KINGDOM OF PRUSSIA, TO 1786

Frederick III and I (1688–1713).—When Frederick III of Brandenburg succeeded his father, the Great Elector, in 1688, Brandenburg-Prussia consisted of four separate groups of lands, scattered across Europe from the lower Rhine in the west to the Memel River in the east and unconnected by any territorial link. The central and largest group comprised Electoral Brandenburg (Old Mark, Middle Mark and New Mark), with the secularized bishoprics of Magdeburg and Halberstadt adjoining it in the southwest and Hinterpommern (central Pomorze) in the northeast; the second group comprised the duchy of Cleves, on the lower Rhine, and the countship of Mark, on the Ruhr River (these two territories were not contiguous); the third group comprised the

countship of Ravensberg and the secularized bishopric of Minden, between the upper Ems and the middle Weser; and finally there was Ducal Prussia in the east, independent of the *Reich*.

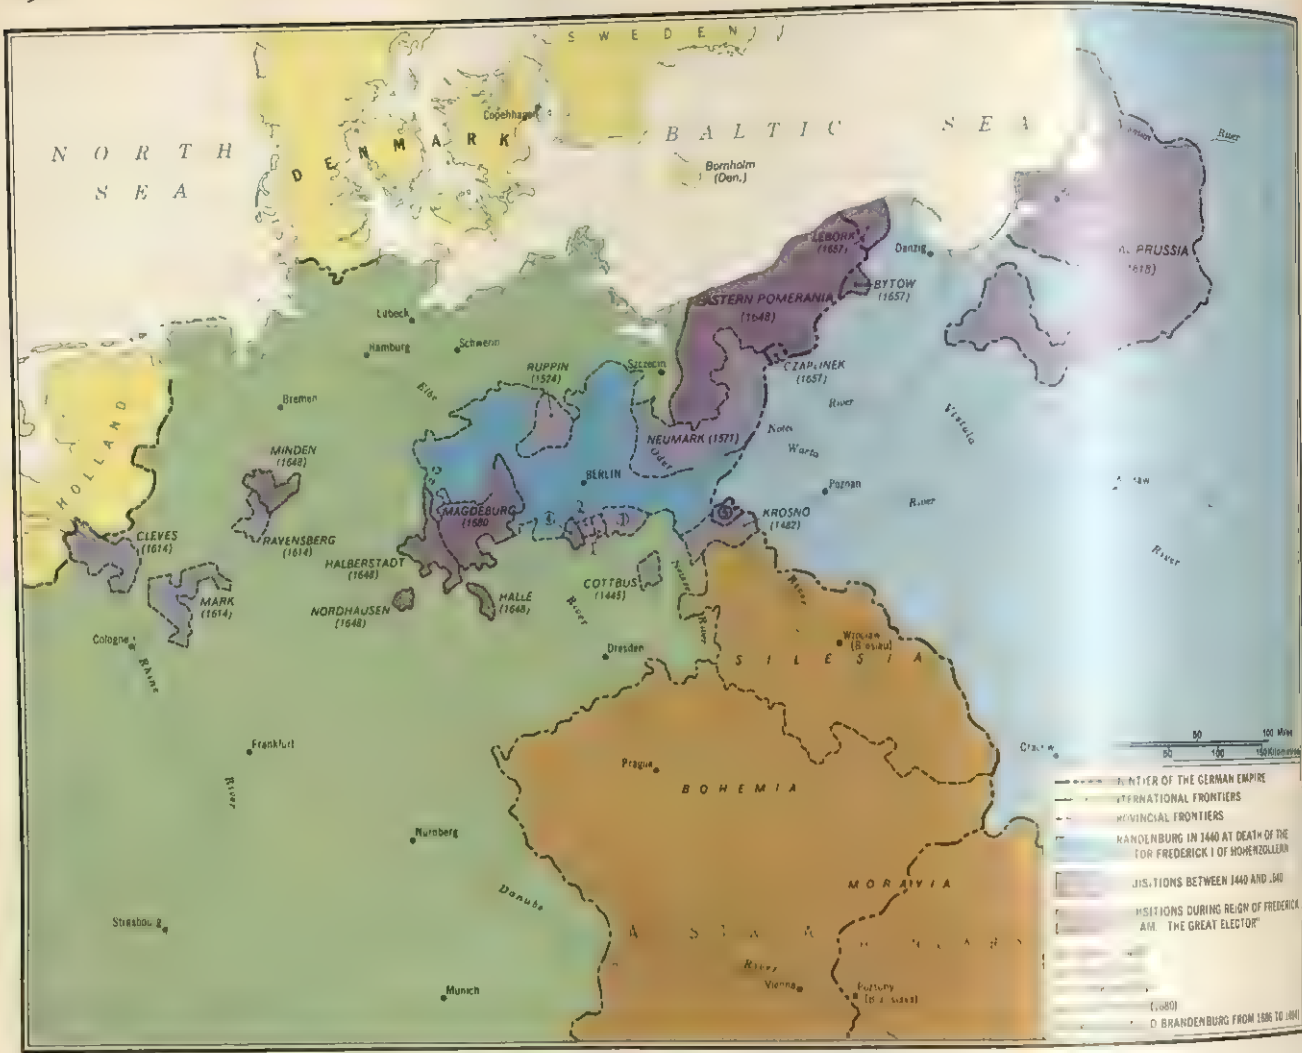

The most significant achievement of the Great Elector's son was to secure the royal dignity for himself, as Frederick I (*q.v.*), king in Prussia; he crowned himself at Königsberg on Jan. 18, 1701, after the Holy Roman emperor Leopold I had consented to his assuming this new status in order to ensure his good will in the forthcoming War of the Spanish Succession. Ducal Prussia thus became the basis of his rank as sovereign king; and the other Hohenzollern possessions, though theoretically they remained within the German *Reich* and under the ultimate overlordship of the emperor, soon came to be treated in practice rather as belonging to the Prussian kingdom than as distinct from it. To these possessions Frederick added the countship of Mörs (adjacent to Cleves) and the countship of Lingen (on the Ems) in 1702 and the countship of Tecklenburg (on Lingen's southeastern border) in 1707.

Frederick William I (1713–40).—Frederick I's son Frederick William I began his reign in 1713 shortly before the conclusion of the Treaty of Utrecht, which assigned to him not only the so-called Upper Quarter of Geldern (see **GELDERLAND**), on the Meuse River adjoining Cleves and Mörs, but also the principality of Neuchâtel and Valengin on the border of France and Switzerland. Through participation in the Northern War he further acquired the southern part of Vorpommern (western Pomorze between the Oder and the Peene River, including Stettin) from the Swedes under the Treaty of Stockholm (1720).

It was Frederick William I who endowed the Prussian state with its military and bureaucratic character. He raised the army to 80,000 men (equivalent to 4% of the population) and geared the whole organization of the state to the military machine. One half of his army consisted of hired foreigners, the other half was recruited from the king's own subjects on the basis of the "canton system." This system made all young men of the lower classes—mostly peasants—liable for military service, though after finishing their training they were given leave for ten months of every year so that they could pursue their normal work. While the upper bourgeoisie was exempt from this military service, the nobles were under a moral obligation, which the king repeatedly emphasized, to serve in the officers' corps. If the social structure had not differentiated the classes or estates, it would have been impossible to maintain so great an army without damaging the economy. Economic policy, which was conducted on mercantilist principles, was in fact designed to satisfy the army's constantly expanding requirements.

This close coordination of military, financial, and economic affairs was moreover complemented by Frederick William I's reorganization of the administrative system, which he transformed into something peculiar to Prussia. To resolve the conflict between the administration of the domains, with its predominantly agrarian outlook and the fiscal administration, with its bias in favour of the town's commercial interests, the king in 1723 fused them both into one great central authority, the *Generaldirektorium* (General Directorate). In the separate parts of the monarchy he likewise merged the corresponding lesser authorities into *Kriegs- und Domänenkammern* (War and Domain chambers), to which the *Landräte* (country counselors) in the open country and the *Steuerräte* (tax counselors) in the towns were subordinated.

The *Generaldirektorium* was initially divided into four departments, each of which was headed by a minister and responsible for a number of provinces. Business was handled collegially, by the voting of ministers and counselors, but in all important matters the decision rested with the king himself. Though he was, formally, the president of the *Generaldirektorium*, the king preferred to communicate with his ministers only in writing: it was from the royal cabinet, with the help of his secretaries, that he controlled the whole life of the state. His autocratic temperament and his fanatical addiction to work found expression in complete absolutism. To his son and successor, Frederick II, he left the best-trained army in Europe, a financial reserve of 8,000,000 thalers, productive domains, provinces developed through large-

THE RISE OF BRANDENBURG-PRUSSIA (1440-1701)

scale colonization (particularly East Prussia), and a hard-working, thrifty, conscientious bureaucracy.

Frederick the Great (1740-86).—Frederick II (*q.v.*) the Great put the newly realized strength of the Prussian state at the service of an ambitious but risky foreign policy. Hailed by Voltaire as “the philosopher king” personifying the Enlightenment and its ideal of peace, Frederick astonished Europe, within seven months of his accession to the throne, by invading Silesia (December 1740). This bold stroke precipitated the War of the Austrian Succession (*q.v.*); and the Austro-Prussian struggle for Silesia continued, with uneasy intermissions, till the end of the Seven Years’ War (*q.v.*) in 1763. Frederick’s wars not only established his personal reputation as a military genius but also won recognition for Prussia as one of the Great Powers. Silesia, a rich province of 150 towns and thousands of villages, with an advanced economy and a flourishing culture, was a considerable acquisition for the Prussian monarchy.

Frederick also had incidentally acquired Ostfriesland (East Frisia, on the North Sea coast) in 1744; and later, at the First Partition of Poland in 1772 (*see* POLAND: *History*), he annexed West Prussia, that is, Polish Royal Prussia, thus at last forming a territorial link between his kingdom in the strict sense and the main block of his German possessions.

Frederick made no substantial changes in the administrative system as organized by his father. To the *Generaldirektorium*, however, he added several specialized departments to deal with matters affecting the state as a whole; e.g., the *Fabrikendepartement*, or Factory Department, instituted in 1740 as the supreme organ of his mercantilist economic policy. After the Seven Years’ War, moreover, the administration of customs and excise was

transferred from the *Generaldirektorium* to a separate *Regie* or organized on French lines. In fact this complex structure of the state produced impressive results, which served primarily to maintain Prussia’s new international status and to meet the needs of defense: the strength of the army was raised to 180,000 men; a financial reserve of 55,000,000 thalers was accumulated, and, in the course of the reign, no less than 300,000 settlers were established. In 1775 the Prussian state (excluding West Prussia) had about 4,900,000 inhabitants.

“Enlightened despotism” was well exemplified in the improvement of the judicial and educational systems and in the promotion of the arts and sciences. Certain features of the Enlightenment in Frederick’s Prussia were indeed unique in Europe. The church, the bureaucracy, and education in general were pervaded by the state’s control over public instruction, which however still allowed a measure of intellectual freedom to the cultured bourgeoisie and, by setting certain moral limits to the state’s absolute authority, prevented it from becoming a tyranny. The freedom of conscience which Frederick instituted was the product not merely of his own skeptical indifference to religious questions but also of a deliberate intention to bring the various churches together for the benefit of the state and to allow more scope to the large Catholic minority of his subjects in relation both to the Protestant majority and to the Evangelical establishment. (S. Sk.)

THE FRENCH REVOLUTIONARY AND NAPOLEONIC PERIOD

Frederick William II (1786-97).—Frederick William II (*q.v.*) was not nearly so considerable a ruler as his uncle, whom he succeeded. He purchased the margraviates of Ansbach and

THE RISE OF PRUSSIA (1701-1806)

Bayreuth from the last representative of the Franconian Hohenzollerns in 1791; and he obtained a far larger territory in the east through the Second and Third Partitions of Poland—first Danzig and all the country between West Prussia and Silesia in 1793, and then Warsaw, the whole basin of the Narew River, and all the country west of the middle Niemen in 1795. He had no real success, however, in the War of the First Coalition against Revolutionary France: having entered it at its inception in 1792, he made the separate Peace of Basel in 1795. By this treaty he consented to France's eventual annexation of the German lands west of the Rhine in return for France's consent to his acquiring, in due course, new lands east of the Rhine in compensation for his losses. (See FRENCH REVOLUTIONARY WARS.)

Frederick William's management of the Prussian economy was less prudent than his predecessor's and finally brought the state's finances into disorder. Even so, his reign saw a notable advance in Prussia in the cultural sphere: music and the drama flourished conspicuously in Berlin, where moreover the monumental Brandenburg Gate was built to typify contemporary aspirations in architecture; and Immanuel Kant (*q.v.*) was lecturing in Königsberg. Law was codified in the *Allgemeines Preussisches Landrecht* in 1794.

Crisis and Defeat (1797-1807).—Frederick William III (*q.v.*) succeeded his father in 1797. By pursuing the policy of neutrality during the Wars of the Second and the Third Coalitions against France (see NAPOLEONIC WARS) he forfeited the respect and the goodwill of the belligerent Powers; and when at last he went to war in 1806 it was too late to avert catastrophe. Meanwhile, however, under the *Reichsdeputationshauptschluss* of 1803 (see GERMANY: History), Prussia had received the secularized bishop-

rics of Hildesheim and Paderborn, the largest share of that of Münster, two large former dependencies of secularized Mainz (Eichsfeld and Erfurt), and numerous smaller places.

Frederick William III's failure to join Austria, Russia, and Great Britain in their coalition of 1805 was largely due to his hope of annexing Hanover (a kingdom in dynastic union with Great Britain). This hope was momentarily fulfilled in 1806, as a consequence of the unfortunate diplomacy of Christian, Graf von Haugwitz (*q.v.*); but by September of that year Napoleon's duplicity had provoked Prussia into war against France. The overwhelming defeat of the Prussians in the Battles of Jena and Auerstädt (*qq.v.*) was followed by the rapid collapse of the state. By the Treaty of Tilsit (1807) the king had to cede all his possessions west of the Elbe and all that had been gained under the Second and Third Partitions of Poland, together with the southern part of what had been gained under the First, so that the monarchy was reduced to Brandenburg, Silesia, the Pomeranian provinces, northern West Prussia (without Danzig), and East Prussia. Furthermore, the state was required to pay an exorbitant contribution to Napoleon's finances and to accept a French occupation of much of its territory.

Reform and Recovery (1807-15).—The backwardness of Prussia was revealed by the disaster of 1806. Administrative, social, and military reforms were clearly overdue, and the king's chief minister, Karl Stein (*q.v.*), seized the opportunity to introduce them. His basic idea was to evoke a positive consciousness of solidarity with the state by allowing the citizens to take a more active part in public affairs; and this idea underlay the emancipation of the serfs (begun in 1807), the measures for local self-government contained in the *Städteordnung*, or Towns Ordinance

(1808), and the reshaping of the central government.

Though Stein was dismissed from office at Napoleon's behest in November 1808, the work of reform was continued. After the less significant ministry of F. F. A. von Dohna and Karl von Stein zum Altenstein, the king in 1810 took Karl August, Freiherr (later Prince) von Hardenberg (*q.v.*), as chancellor of state or prime minister. Hardenberg had no particular liking for Stein's idea of self-determination and preferred the absolutist form of governing, though he showed some sympathy for liberal principles in regard to individual branches of enterprise; but for practical purposes at least he was ready to proceed with the reforms. To facilitate the levying of the tribute exacted by France, he made some modest concessions of a constitutional nature: for instance, the summoning of an Assembly of Notables (on French lines) in 1811 and that of a Representative Assembly of the Nation (*Nationalrepräsentation*) in 1812. He also issued ordinances to regulate the accession of the emancipated peasants to the ownership of land (from 1811) and granted equality of civil rights to the Jews (1812). In the economic sphere he introduced freedom to choose one's trade, abolishing the restrictive powers of the guilds.

The Napoleonic domination of Europe, meanwhile, was provoking a great upsurge of national sentiment, which was felt in Prussia no less strongly than in the other German states and was eventually to manifest itself in the War of Liberation (1813-14; see *GERMANY: History*). The transformation of the Prussian army from a largely mercenary force into a genuinely national organ was begun by Gerhard von Scharnhorst (*q.v.*), who thus prepared it for the part that it was to play.

At the same time the Romantic movement in the intellectual and artistic field further stimulated patriotism and the cult of liberty, to the service of which it even brought its interpretation of history. The foundation, in 1809, of the Friedrich Wilhelm University in Berlin, with Wilhelm von Humboldt (*q.v.*) as its chief promoter, magnificently affirmed Prussia's spirit in the aftermath of defeat.

Hardenberg adroitly steered Prussia through the difficult year 1812, when Prussia and Austria, in enforced alliance with France, had to participate in Napoleon's attack on Russia (see again *NAPOLEONIC WARS*). Napoleon's retreat from Moscow was the signal for a rising against the French. By the Convention of Tauroggen on Dec. 30, 1812, the Prussian general Johann (Hans) Yorck (*q.v.*) von Wartenburg withdrew his corps from fighting against the Russians; by the Treaty of Kalisz, on Feb. 28, 1813, Prussia's momentary neutrality was replaced by an alliance with Russia; and on Aug. 12, 1813, Austria also declared war on France. The Prussian army, with G. L. von Blücher and A. Neidhardt von Gneisenau (*qq.v.*) as its leaders, took a major part in the Battle of Leipzig, in the campaign of 1814 in France, and in the Waterloo campaign of 1815.

The Congress of Vienna (1814-15).—The Congress of Vienna (*q.v.*) did not restore Ostfriesland, Lingen, Hildesheim, Ansbach, or Bayreuth to Prussia; it allowed Neuchâtel to join the Swiss Confederation and to be detached from the Prussian monarchy, though remaining a personal possession of the Prussian king; and Prussia recovered nothing of its gains under the Third Partition of Poland and only Danzig, Posen (Poznan), Gnesen (Gniezno), and Thorn (Torun) of its gains under the Second. But the rest of what Prussia had possessed in 1803 was restored practically entirely by the Congress, with a considerable addition of new territory. This new territory comprised (1) areas taken from the Kingdom of Saxony, which were merged with older Prussian territories on the left bank of the Elbe to form the Province of Saxony (Provinz Sachsen), apart from the Lusatian areas, which were divided between Brandenburg and Silesia; (2) areas west and east of the Rhine, which were merged with older Prussian territories to form the Rhine Province (Rheinprovinz) and the Province of Westphalia (Provinz Westfalen); and (3) the formerly Swedish part of Vorpommern, with Rügen Island, which was merged with the rest of the Pomeranian territory to form the Provinz Pommern. Moreover, by the Peace of Paris (1815), France ceded Saarlouis and Saarbrücken to Prussia, which incorporated them in the Rhine Province.

With its major territorial axis shifted from eastern Europe to western and central Germany, Prussia was henceforth the only Great Power with a predominantly German-speaking population. It was thus Austria's potential rival for hegemony in the German Confederation (*Deutscher Bund*), which the Congress also created. The northeastern provinces of the monarchy, however, namely Prussia proper (subdivided between West Prussia, which included Danzig, and East Prussia, to which Thorn was attached) and Posen (a grand duchy), were kept outside the Confederation's boundaries as also was Neuchâtel. In foreign policy Prussia adhered, with Austria and Russia, to the Holy Alliance (*q.v.*); and for internal affairs a conservative and absolutist line was taken in accord with the general spirit of the Restoration. (E. W. Z.)

THE KINGDOM FROM 1815

The reforming impulse flagged after 1815. Frederick William III promised in May 1815 to introduce a constitution, but failed to carry out his promise; and all that remained of it was an assurance that the state would not contract new loans without the consent of a representative assembly. The army lost much of its new spirit when Hermann von Boyen, victor of war from 1814, resigned in 1819. On the other hand the educational system remained the best in Europe, the University of Berlin in particular enjoying an unrivaled reputation. The major parts of the kingdom's western provinces, however, had never been Prussian before and, being mainly Roman Catholic, were alien to Prussia in outlook. This produced a fierce conflict between church and state over mixed marriages in the years 1836-40, with bishops in prison and sees left vacant. Administratively much was done to bind the provinces together. The estates of the individual provinces gradually acquired a Prussian consciousness. The bureaucracy established a high standard of efficiency and honesty, which was at this time unique in Europe. In 1818 a simplified tariff, with moderate customs dues, was introduced for the entire kingdom and this tariff became the basis for the *Zollverein* (customs union) established in 1834, which by 1852 included all the German states except Austria and Hamburg.

Frederick William IV and the Revolution of 1848.—In 1840 Frederick William IV (*q.v.*) succeeded to the throne on the death of his father. A product of the Romantic movement, he aspired to revive in Prussia his imaginary conception of the Middle Ages. He called off the conflict with the Roman Church; and in 1844 he actually attended the celebrations which marked the completion, after many centuries, of the Cologne Cathedral—the first king of Prussia to enter a Roman Catholic building. Though opposed to modern constitutionalism, he aspired to create Estates of the Realm on a medieval pattern. Also he wished to raise a loan in order to build the *Ostbahn*, a railway to link Berlin and Königsberg. In 1847 therefore he brought the provincial Diets together at a "United Diet" (*Vereinigter Landtag*) in Berlin. The Diet demanded a promise of regular meetings; and, when this was refused, it refused in turn to endorse the loan for the *Ostbahn*. The Diet was therefore adjourned after barren debates.

In March 1848 revolution broke out in Germany, inspired by the February revolution in France (see *GERMANY: History*). On March 16 and 18 there was street fighting in Berlin. Though the army was victorious, the king lost his nerve. He withdrew the army from Berlin on March 19, and for a brief period put himself at the head of the revolution. A liberal government was set up under Ludolf Camphausen and David Hansemann; a Constituent Assembly was summoned. Radicals dominated this assembly and the king was gradually turned against it by the army officers who surrounded him. The Assembly was moved in October to the provincial town of Brandenburg. Its members called on the citizens of Prussia to refuse to pay taxes, but the call was abortive; the army reoccupied Berlin, and in December the Assembly was dissolved. Meanwhile a conservative ministry under Friedrich Wilhelm, Graf von Brandenburg (a son of King Frederick William II's last morganatic marriage), had replaced the two short-lived ministries which had succeeded Camphausen's. A more moderate Assembly was elected, but this, too, proved obdurate. A third Assembly was elected on a more restricted franchise in February 1849.

The Constitution of 1850.—Finally the king imposed a constitution by decree in February 1850. This constitution remained unchanged until 1918. Prussia received a parliament with two chambers. The First or Upper Chamber, officially named the *Herrenhaus* (House of Lords) in 1854, was composed of representatives of the great landed proprietors and of the large towns, and of members nominated by the king, some for life and some with hereditary right. The Second or Lower Chamber was elected by all taxpayers, divided into three classes according to the taxes paid. Though this was a narrow franchise, it was wider than that established in England by the Reform Bill of 1832. The constitution gave the chambers defined rights. Their consent was necessary for legislation; and, though the existing taxes were confirmed in perpetuity, the chambers had to endorse the annual expenditure of money in the budget. The king retained the unrestricted choice of ministers, but it was difficult for them to govern against the express wish of the chambers. The constitution, in fact, corresponded closely to that of England in the 18th century. It appeared inadequate by contemporary liberal standards; but its retention in the years of reaction after 1850 gave Prussia a higher standing than Austria in liberal eyes.

The German Question, 1848-50.—During the revolution of 1848 Frederick William IV aspired to lead the movement for German unification. In March 1848 he declared: "Prussia henceforth merges into Germany"; and he harboured the fantastic idea that all Germany outside Prussia should send representatives to the Prussian Assembly. When this idea miscarried, he regarded the German National Assembly at Frankfurt with suspicion so long as it was under Austrian leadership. But, when Austria forfeited the leadership at Frankfurt by propounding a unitary constitution for the mainly non-German Habsburg empire, Frederick William was tempted to accept the German imperial crown, which was offered to him by a delegation from Frankfurt on April 3, 1849. He was dissuaded with difficulty by his conservative advisers; and grudgingly announced that he could not accept the crown unless it were offered to him by the German princes. He and his friend Joseph Maria von Radowitz (*q.v.*) then tried to build the Erfurt Union on conservative principles and on a "little German" (*kleindeutsch*) basis; i.e., as a union of the German states without Austria. In 1850 Austria challenged this union. Frederick William IV and his conservative ministers shrank from war, and Prussia was obliged to abandon its ambitions by the Convention of Olmütz (Olomouc; Nov. 29, 1850). The old German Confederation was restored; and Otto von Bismarck (*q.v.*) became Prussia's representative at the Frankfurt Assembly. Graf von Brandenburg died during this crisis and was succeeded by Otto, Freiherr von Manteuffel, who ran Prussia on cautious conservative lines for the following eight years.

The "New Era" and the Constitutional Conflict.—Frederick William IV became insane in 1857. His brother took over as regent in 1858 and became king as William I (*q.v.*) on Frederick IV's death in 1861. William I appointed a liberal ministry under Karl Anton, prince of Hohenzollern-Sigmaringen, a Roman Catholic, and for nearly four years Prussia experienced the so-called New Era, during which it was hoped that Prussia would win the leadership of Germany by the force of moral example. But dispute soon arose between the king and the chambers.

William I was a soldier by training. He knew the deficiencies of the Prussian army and wished to remove them. The army establishment had remained unchanged since 1815; the population of Prussia had greatly increased. As a result, a third of the young men escaped military service—in theory universal. Albrecht von Roon (*q.v.*), the minister of war, produced a comprehensive scheme of military reform: artillery and equipment were to be modernized; more barracks were to be built; but at the same time the *Landwehr*, or militia, was to be reduced in importance. The *Landwehr* elected its own officers, who usually did not belong to the hereditary officer class. Roon disliked this democratic principle and wished to make the standing army dominant. The Lower Chamber did not oppose army reform, but wished to preserve the *Landwehr*, which was a symbol both of liberalism and of the struggle for liberation during the Napoleonic Wars. The conflict which

followed was over the character of the army, not over its size or cost.

By the constitution, the taxes were imposed permanently, unless revised. The Lower Chamber therefore could not cut off supplies from the government: it could only refuse to authorize the expenditure of money that had been already collected. In 1860 it authorized additional expenditure on the understanding that no permanent steps, such as the building of new barracks, would be undertaken. Roon disregarded this bargain. In 1861 the Chamber again authorized the additional expenditure, but with an explicit warning that after this it would refuse unless its demands for retaining the *Landwehr* and for reducing the period of military service from three to two years were met. Again Roon disregarded the demands of the Chamber. When it stood firm for its demands in March 1862, it was dissolved, and the New Era ministry resigned; and when the new Chamber still rejected the military budget, William I threatened to abdicate. As his son the crown prince Frederick William (later king as Frederick III) also supported Roon's program, this would have settled nothing. Roon persuaded the king to appoint Otto von Bismarck minister-president (September).

Bismarck devised an ingenious theory. The constitution provided that the budget should be agreed between the two chambers and the king. Bismarck argued that, since the Lower Chamber had failed to agree with the Upper and with the king, there was "a gap in the constitution"; and he claimed that it was the king's duty to spend money without a budget until agreement was reached. This was not much of a theory, and Bismarck himself repudiated it later, but it served its turn. The liberals were helpless. It would have been unconstitutional to refuse the taxes. They could only protest in constitutional form. Bismarck took a middle course. Though he defied the attempt of the Chamber to determine military policy, he also resisted the proposals of Edwin von Manteuffel and others to scrap the constitution altogether.

During the crisis of 1863-64 over the Schleswig-Holstein question (*q.v.*), the Lower Chamber persisted in rejecting the military budget, but this did not prevent Prussia's going to war against Denmark. It was Prussia's Seven Weeks' War (*q.v.*) against Austria in 1866 that ended the constitutional crisis; Bismarck apologized for the illegal expenditure of money; and in September the two chambers passed an Act of Indemnity.

Bismarck's Wars and the Foundation of the Reich.—For Prussia's foreign policy in the 1860s see, besides the two articles indicated in the preceding paragraph, BISMARCK, OTTO, PRINCE VON; GERMANY: History. The Danish War of 1864 led to an Austro-Prussian condominium over Schleswig-Holstein. The Seven Weeks' War was followed by the annexation not only of Schleswig-Holstein but also of Hanover, Electoral Hesse, Nassau, and Frankfurt am Main to Prussia, which now extended without interruption across Germany and contained two-thirds of Germany's population.

The Franco-German War (*q.v.*) of 1870-71 established Prussia's position as the leading state in the imperial German *Reich*. William I of Prussia became German emperor on Jan. 18, 1871; the Prussian army virtually absorbed the other German armed forces, except the Bavarian army, which remained autonomous in peacetime. Bismarck combined the offices of imperial chancellor and Prussian minister-president, except during an interval in 1872-73 when Roon held the latter post.

Internal Affairs, 1871-1918.—In 1872 the Local Government Act extended to the rural areas the autonomous administration which Stein had in 1808 created for the towns. Prussia was now a predominantly industrial state. The Junker gentry, or landowners, who had a monopoly of public employment at the beginning of the 19th century, held only 17% of the posts at the end, and these only in the provinces east of the Elbe River. (For the anti-Catholic *Kulturkampf*, see again GERMANY: History.)

William I died in 1888, and after the short reign of his son Frederick III (*q.v.*; March-June 1888), the latter's eldest son became emperor as William II (*q.v.*). The three-class franchise had become increasingly unrepresentative and aroused much discontent. Bismarck did nothing to change it, though he described

PRUSSIA (1806-15)

it as "the most miserable franchise in existence." His successor Leo, Graf von Caprivi (*q.v.*), who became chancellor of the *Reich* and Prussian minister-president in 1890, ruled in Germany with the support of a left-wing coalition in the *Reichstag*. In 1892 he relinquished the position of Prussian minister-president, which was taken by Botho, Graf zu Eulenburg. To satisfy his left-wing supporters, Caprivi pressed for a reform of the Prussian franchise. Eulenburg answered by demanding an imperial law against the Social Democrats. Each man was seeking to interfere in the other's sphere. Deadlock was resolved only when William II dismissed both of them (Oct. 28, 1894). Thereafter the office of Prussian minister-president was again combined with that of imperial chancellor.

Johannes von Miquel, the finance minister, introduced important reforms during the 1890s, which made the distribution of taxation more equitable between the richer and poorer classes. Nothing was done to change the three-class franchise; and the Prussian Lower Chamber was now dominated by the conservative landowners. They controlled the government of Prussia, but this control counted for less as the imperial government developed in size and importance. Only the army gave the Prussian Junkers a disproportionate influence in German life.

Reform of the Prussian franchise became a burning question whenever the *Reichstag* had a left-wing majority, as it often had. Chancellor Bernhard von Bülow (*q.v.*) pressed the question in 1907, when he appeared to be transforming Germany into a parliamentary state with the support of the "Bülow bloc." His successor, Theobald von Bethmann Hollweg (*q.v.*), also regarded it as the key point in the development of a democratic system. Solemn promises of franchise reform were made on the outbreak

of World War I in 1914; and a reform law was introduced in the Prussian Chamber in 1917. It was still being discussed when the German revolution of 1918 and the abdication of William II swept away the old order.

THE END OF PRUSSIA

The revolution ended the Prussian monarchy and the three-class franchise. It also ended the connection between the chancellor of the *Reich* and the Prussian minister-president. Prussia, which lost part of Silesia, Posen, West Prussia, Danzig, Memel, northern Schleswig, some small areas on the Belgian frontier, and the Saar district as a result of the Treaty of Versailles or the ensuing plebiscites, became a *Land* under the Weimar Republic, with more restricted powers than before and with little influence on the government of the *Reich*. Its parliament was now elected by universal suffrage; and this always produced a left-wing majority. Between 1918 and 1932 Prussia was ruled by the Social Democrats, sometimes alone, sometimes with the support of the Centre. The outstanding personality was Otto Braun, the Social Democratic prime minister. The *Land* controlled the police force. Hence the Social Democratic government of Prussia was regarded as the essential defense of German democracy.

In April 1932 the coalition of Centre and Social Democrats lost their majority in the Prussian parliament at a general election. Otto Braun resigned; but, as the opposition was divided between Communists and National Socialists, no coalition could be formed to replace that which had been defeated. Franz von Papen (*q.v.*), chancellor of the *Reich* from June 1932, used this situation as an excuse to end Prussian autonomy. He was appointed *Reichskommissar* for Prussia by Pres. Paul von Hindenburg in July.

TERRITORIAL CHANGES IN PRUSSIA (1815-1919)

Otto Braun was absent, ill. Karl Severing, the Prussian minister of the interior, agreed to yield to force and was formally removed from his office by two policemen. The Prussian government appealed to the High Court at Leipzig, which in 1933 ruled that the expulsion had been unconstitutional, but that the constitution provided no remedy by which the illegality could be redressed. Meanwhile Papen, who had temporarily been replaced by Kurt von Schleicher as chancellor, was finally replaced by Adolf Hitler himself, who in April 1933 appointed Hermann Göring (q.v.) as minister-president and minister of the interior. In this way control of the Prussian police passed to the Nazis. The Prussian constitution was set aside, and the legislature abolished, though Prussia remained a unit for administrative purposes.

In 1945, after defeat in World War II, Germany came under the four-power control of the victorious allies—Great Britain, the United States, the U.S.S.R., and France. Northern East Prussia was annexed by the Soviet Union; the rest of the Land east of the Oder-Neisse line was transferred to Poland; the remainder was divided between the Soviet, British, and French zones of occupation. One of the few acts of the Allied Control Council was formally to abolish Prussia (March 1, 1947).

PRUSSIC ACID: see HYDROCYANIC ACID.

PRYNNE, WILLIAM (1600-1669), English Puritan pamphleteer, antiquarian, and parliamentarian, whose ears were twice shorn as punishment for his opposition to the religious policy of William Laud, was born at Swainswick near Bath, the son of a farmer, Thomas Prynne. He was educated at Bath Grammar School and at Oriel College, Oxford, and was called to the bar at Lincoln's Inn in 1628. From 1627, when his first pamphlet was published, Prynne emerged as an opponent of Arminianism in church doctrine and of ceremonialism in church services, and thereby attracted the hostility of William Laud (bishop of London, 1628-33, archbishop of Canterbury, 1633-45).

Prynne's famous attack on the theatre and stage plays, *Histriomastix: the Players Scourge or Actors Tragedy* (1632; dated 1633), alleged that plays were evil and corrupted morals. It claimed that kings and emperors who had supported the theatre had met violent deaths, and its vicious denunciation of actresses

was assumed to apply also to Queen Henrietta Maria, who at the time of its publication was taking part in a masque. Through Laud's influence Prynne was imprisoned in February 1633 in the Tower of London. On Feb. 17, 1634, he was sentenced by the Star Chamber to be imprisoned for life, fined £5,000, expelled from Lincoln's Inn, degraded from his Oxford University degree, and set in the pillory, where he was to lose both his ears. The latter part of the sentence was carried out on May 7 and 10, when his ears were partly cut off.

Prynne continued his writings while in the Tower, attacking James I's *Book of Sports*, reissued in 1633, which permitted games on Sunday, in *A Divine Tragedie Lately Acted* (1636), and Matthew Wren, bishop of Norwich, and other bishops who supported Laud in *Newes from Ipswich* (1636). On June 14, 1637, Prynne was brought before the Star Chamber with two other puritans, John Bastwick and Henry Burton, and was again sentenced. On June 30 the stumps of his ears were shorn off in the pillory at Westminster and he was branded on the cheeks with the letters S.L., meaning "seditious libeler," though Prynne interpreted them in verse as "Stigmata Laudis" (the marks of Laud). He was later removed to Carnarvon Castle and to Mount Orgueil Castle in Jersey.

When the Long Parliament met in November 1640 it ordered Prynne to be freed and on April 20, 1641, his sentences were declared illegal. He then attacked the Roman Catholics and in 1642 defended Parliament's resort to arms against Charles I. He showed a vindictive energy in the prosecution of Laud, which resulted in the archbishop's execution in January 1645. Having been entrusted (May 1643) with the search of Laud's papers, he published a mutilated edition of his diary, entitled *A Breviate of the Life of William Laud* (1644), and also *Hidden Workes of Darkenes Brought to Publike Light* (1645) to prejudice the case against Laud. Prynne, although opposed to ceremonialism, favoured a national church controlled by the king as head of the state and issued a series of tracts against the Independents. He also violently opposed the Presbyterian system and in his *Four Serious Questions* (1645) and *A Vindication of Four Serious Questions* (1645) he denied the right of any church to excommunicate except by leave of the state. He remained throughout an enemy of individual freedom in religion.

Prynne took the side of Parliament against the army in 1647. He was returned as a member for Newport in Cornwall in November 1648. He at once opposed the demand for the execution of Charles I and as a result was among those members excluded by the purge of Col. Thomas Pride on Dec. 6, 1648. Imprisoned for resisting this expulsion, he was released in January 1649 and retired to Swainswick. In June he was assessed for the monthly contribution levied on the country by the Commons to support the army, but refused to pay and published *A Legal Vindication of the Liberties of England* (1649), arguing that no tax could be raised without the consent of the two Houses (the Lords had recently been abolished). As a result, he was imprisoned by the army from June 1650 to February 1653 and on his release renewed his pamphleteering activities. When the Rump Parliament was restored by the army on May 7, 1659, Prynne was refused admittance, but on Feb. 21, 1660, with Gen. George Monck's support, he took his seat. He was returned for Bath to the Convention Parliament (1660), where he supported the restoration of Charles II, and to the Parliament elected in 1661.

Prynne was more notable as an antiquarian than as a politician. His knowledge of the national archives, unrivaled in that age, was acknowledged by his appointment in 1660 as keeper of the records in the Tower. In that office he did much to rescue the documents there from neglect and to secure their proper preservation. His historical writings, though devoid of style and orderly arrangement, have a lasting value because of the original records printed in them. They include *An Exact Chronological Vindication and Historical Demonstration of Our British, Roman, Saxon . . . Kings Supreme Ecclesiastical Jurisdiction, over all Spiritual or Religious Affairs . . . Within Their Realms*, covering the period to the death of Edward I, three volumes (1665-68); *Aurum Reginae, or a Compendious Tractate and Chronological*

Collection of Records in the Tower and Court of Exchequer Concerning Queen-Gold (1668); and *Brief Animadversions on . . . the Fourth Part of the Institutes of the Lawes of England . . . compiled by Sir E. Coke* (1669). Prynne died unmarried on Oct. 24, 1669, at Lincoln's Inn, London.

See E. W. Kirby, *William Prynne* (1931), which contains a bibliography of his writings; W. M. Lamont, *Marginal Prynne, 1600-1669* (1963).

PRYTANEUM, the town hall of a Greek city state. These states normally had a building which housed the chief magistrate (sometimes called prytanis) and the common altar or hearth of the community. There ambassadors, distinguished foreigners, and citizens who had done signal service were entertained. There is evidence for a prytaneum at Sigeum in the Troad in the 6th century B.C., at Dreros in Crete in the 3rd (where an oath by Hestia is taken in the prytaneum), and at many other places at various dates, among them Cyzicus, Erythrae, Priene, Ephesus, Epidamnus, and Rhodes. At Athens one sign of the unification of Attica attributed to Theseus was the creation of a single prytaneum (Thucydides, book ii, 15). This was the ancient seat of the chief archon (*q.v.*) and was situated on the north slope of the Acropolis.

After the Persian invasion administration shifted to the market place (agora), where the council (*boule; q.v.*) then met and where c. 470 B.C. a round building, now identified as the Tholos (see **ATHENS: Topography and Antiquities: The Agora**), was erected as meeting place and dining hall for the *prytaneis*, the committee of the council. This building was later known as the *prytanikon* and is to be distinguished from the prytaneum, which continued to be used for honorific meals.

Prytaneum was also the name of an Athenian law court. In it sat the "king" (*basileus*, one of the archons) and the four "tribe kings" (*phylobasileis*). In the 5th century and later it tried cases of homicide due to an unknown person, an animal, or an inanimate object. It was probably the survival of an ancient court set up as the main court of the state at the newly instituted prytaneum after the unification of Attica. In an amnesty law attributed to Solon near the beginning of the 6th century the prytaneum is mentioned as one of a number of courts which had pronounced sentence of exile. It is perhaps significant that court fees at Athens were known as *prytanea*.

PRZEMYSL, a town in Rzeszow wojewodztwo (province), Poland, lies on the San River, near the frontier of the U.S.S.R., and at the border of the Carpathian Mountains and the sub-Carpathian lowlands. Pop. (1960) 47,442. The town began as a fortress on the old route leading south through the Carpathians. It was the object of dispute in the 10th century between Poland and Ruthenia. Occupied at the end of the 11th century by Ruthenian princes, it came into Polish hands in 1340. It acquired city rights in 1389 and numerous privileges, and developed into a large commercial and cultural centre. After the first partition of Poland in 1772 it was taken by Austria, returning to Poland in 1918.

Its long history has left Przemyśl many old buildings, including the castle, rebuilt in the 17th century, and the 15th-century cathedral, often rebuilt and enlarged. There are two museums. Industries include metalworking, a knitted-goods factory, and timber working. The town and its surroundings are popular with tourists. (T. K. W.)

PRZEMYSL, SIEGES OF. An Austrian-held fortress town on the San River in modern Poland. Przemyśl (*q.v.*) underwent two major sieges in the first year of World War I. Its defense and its attack tied up large numbers of men and huge quantities of matériel, but otherwise they had little effect on the course of the war.

Przemyśl was protected by a ring of forts 36 mi. in circumference. Some were of recent construction, but the fortress as a whole was not strictly up to date. To clear the foreground in front of the fortified line no fewer than 18 villages and about five miles of forest were leveled to the ground on mobilization.

During August 1914, the first month of the war, Austrian armies advancing eastward through Galicia had been met and defeated by the Russians at Lemberg (modern Lvov); by mid-September the Austrians had fallen back from the San River line toward Cracow, leaving the garrison at Przemyśl to hold as best it could. By Sept. 24 the Russian investment of the fortress was complete, the siege being undertaken by Radko-Dimitriev's 3rd Army. While arrival of Russian siege artillery was delayed by the state of the communications, the Austrians renewed the offensive early in October. In the hope of capturing Przemyśl before the progress of the enemy offensive compelled the raising of the siege, Radko-Dimitriev carried out several violent assaults between Oct. 5 and 8; they broke down with heavy loss, and the approach of the Austrian 3rd Army necessitated the withdrawal of the investing forces. The fortress was entered by Austrian infantry of the field armies on Oct. 11, when the Russians retreated east of the San.

During the Austrian attempts to force the San line, which lasted throughout October, the fortress lay in the centre of the battle line, and its garrison took an active part in the operations. Its reserves of supplies and material were largely drawn on by the field armies, from whose operations great results were expected at the time. But when the offensive proved fruitless and Russian pressure necessitated a retirement that would leave the fortress again isolated, special efforts were made hastily to re-provision it. They were so far successful that the fortress, commanded by General Kusmanek, was enabled to hold out for 4½ months in the second siege which began on Nov. 9.

The second siege was undertaken by a specially formed 11th Army under General Selivanov, consisting of four divisions of second-line troops. It had been decided to reduce the fortress by blockade rather than by assault. During November and December such fighting as occurred was initiated rather by the sorties of the garrison than by the attacks of the besiegers. During February and March 1915 the Austrian armies made repeated but unsuccessful efforts to relieve the fortress.

Meanwhile the Russians had gradually closed in and had commenced a systematic bombardment of the fortress. On March 13 they carried the advanced positions on its north front. Kusmanek's situation was now desperate; his supplies and munitions were almost exhausted, and the final effort of the field armies to come to his rescue had been abandoned. He attempted to save a portion of the garrison by a breakthrough to the east, but the effort, made on the morning of the 19th, was soon brought to a standstill. On the morning of March 22 Kusmanek surrendered after destroying the works and military stores as far as possible. The garrison then numbered about 110,000.

The Russians did not hold the fortress for long. At the beginning of May, Field Marshal Mackensen's offensive on the Dunajec broke through the Russian line and drove their armies back to the San. On May 30 the Austrians attacked on the southwest but made little progress; the Germans, attacking with their heavy artillery on the north of the fortress, made short work of the northern group of forts. On the night of June 2 the Russians abandoned the fortress.

Przemyśl served no strategic aim commensurate with the efforts expended on its defense and attempted relief. Its resistance during the first siege was of value to the Austrians when their armies again advanced to the San, in assuring to them a bridge-head over the river. But during the second siege Przemyśl was an embarrassment rather than a source of strength and led to several ill-considered efforts at relief, which cost the Austrian field armies dearly.

The fortress did not control any line of supply vital to the Russian armies operating west of it toward Cracow, since there was a railway available through Jarosław. The Russians could therefore afford in the second siege to resort to a simple blockade by second-line troops, so that the fortress did not even weaken their field armies to any appreciable extent.

(A. P. W.)

PRZHEVALSKY (PRJEVALSKY), **NIKOLAI MIKHAILOVICH** (1839–1888), Russian traveler, contributed by his explorations and route surveys perhaps more than any other of his generation to the unveiling of central Asia. He was born near Smolensk on March 31, 1839, and was educated at the Smolensk gymnasium. In 1855 he joined an infantry regiment; in 1856 he became an officer. From 1864 to 1886 he taught geography in the military school at Warsaw. The next year he was sent to Irkutsk, and in 1870 he set out from Kyakhta, southeast of Lake Baikal, traveled through Urga (Ulan Bator), and crossed the Gobi Desert to Kalgan (Chang-chia-k'ou), 100 mi. (160 km.) from Peking. He visited Mongolia and then returned to Urga. His second journey began at Kulja in 1876 and took him southeastward across the Tien Shan and Takla Makan, for nearly 200 mi. (320 km.) along the foot of the Astin Tagh, and back by the same route. He set out from Zaisan on his third journey in 1879, crossed Dzungaria and continued southward over the Astin Tagh to within 170 mi. of Lhasa, which he was not allowed to visit. He then turned eastward, partly following the line of the upper Yellow River, and crossed the Gobi to Kyakhta. The fourth journey began at Urga in 1883 and led across the Gobi, south of Koko Nor (Ch'ing-hai) and Tsaidam to the Astin Tagh and Kunlun Mountains and then over the Tien Shan to Issyk-Kul. He had intended to lead another expedition, but died at Issyk-Kul on Nov. 1, 1888. Przhevalsky made valuable collections of the vegetation and animals of the regions he visited and his discoveries include the wild camel and the only known wild horse, named after him Przhevalsky's horse (*Equus przewalskii*). The accounts of his first two journeys were translated into English: E. M. Morgan, *Mongolia, the Tangut Country, and the Solitudes of Northern Tibet* (1876) and *From Kulja, Across the Tian-Shan to Lop-nor* (1879).

See N. M. Karataev, *Nikolai Mikhailovich Przheval'skii* (1948).

(A. M. F.)

PSALMANAZAR, GEORGE (c. 1679–1763), French literary impostor, who published fictitious works on Formosa, was born in the south of France about 1679, of Catholic parents. After his education in Franciscan and Jesuit schools he set out on a wandering life, traveling in Germany and the Low Countries on a forged passport as a native of Japan and under the name by which he was subsequently known. He enlisted in the army of the elector of Cologne and, while still posing as a Japanese, was taken up by an English army chaplain, the Rev. W. Innes, who baptized him, received him into the Church of England, and furthered the imposture by presenting him to Henry Compton, bishop of London. He now posed as a Formosan and translated the Catechism into "Formosan," a language which he himself had invented. He hoodwinked the learned of his time and his *Historical and Geographical Description of Formosa* (1704) and *Dialogue Between a Japanese and a Formosan* (1707) were well received. When doubts of his authenticity arose he attempted to answer objections but soon retired into the obscurity and poverty of a hack writer. In his last years he was a model of rectitude. He died in London on May 3, 1763.

His *Memoirs of . . . Known by the Name of George Psalmanazar* were published in 1764.

See P. W. Sergeant, *Liars and Fakers* (1926).

(H. G. WHE.)

PSALMS, BOOK OF (also called **PSALTER**), a book of the Old Testament. It is entitled in Hebrew TEHILLIM, "Songs of Praise," because it was used from the earliest stages of its present edition as the hymnal of the Second Temple in postexilic Judaism. It belongs to the third canon of the Hebrew Bible known as *Kethubim*, or "Writings" (Hagiographa), together with Job, Proverbs, the Five Scrolls or *Megilloth*, Daniel, Ezra-Nehemiah, and Chronicles.

As all pious Jews in Roman times knew the psalms by heart, Jesus and the early Christians often referred to them. The Psalter became the basis of the Christian as well as Jewish liturgies. No other book of hymnody is common today to all sections of Jewry and Christendom. The psalms are often quoted in the New Testament, usually in the Greek translation of the Septuagint.

The Catholic churches (Greek and Roman), respectively using

the Septuagint and the Vulgate (which follows in this respect the Septuagint), designate the psalms with numbers which differ at times from those of the Hebrew tradition (respected by Jews and Protestants). Modern Roman Catholic scholars, however, are beginning to return to the Hebrew usage. In the Greek-Latin designation, the Hebrew Pss. 9-10 are counted as Ps. 9; Ps. 11 is known as Ps. 10; etc. Other variations are:

Hebrew	Septuagint-Vulgate
114-115	113
116:1-9	114
116:10-19	115
117-146	116-145
147:1-11	146
147:12-20	147

In addition, the Septuagint (Greek) Bible adds a Ps. 151, the Hebrew text of which was discovered among the Dead Sea Scrolls.

Division and Superscriptions.—The Hebrew manuscripts of the Book of Psalms include five doxologies which divide it into five sections, perhaps in imitation of the five books of the Pentateuch: (1) Pss. 1-41; (2) Pss. 42-72; (3) Pss. 73-89; (4) Pss. 90-106; (5) Pss. 107-150. This division, however, appears to be artificial. The superscriptions which are found at the head of most of the poems of the Psalter show that there are several collections, which probably represent earlier stages before the final edition of the book. Such collections may have been:

1. Pss. 3-41, which bear the superscription "To David," except for Ps. 10 (which is clearly the second part of Ps. 9, with which it forms an alphabetic acrostic) and Ps. 31 (which however bears the superscription in the Greek).

2. Pss. 51-72, also ascribed "To David," except Ps. 71 (which bears the superscription "To Solomon"). After Ps. 72 comes the marginal comment, "End of the prayers of David the son of Jesse."

3. The Psalms of Asaph (Pss. 50 and 73-83) may well have formed a separate collection, which was closed before the addition of the second group.

4. The Psalms of the Sons of Korah (Pss. 42-49; 84-85; 87-88).

5. The Psalms of Heman (a son of Korah), the Ezrahite (Ps. 88), and of Ethan, also an Ezrahite (Ps. 89).

6. The Psalms of Yahweh-King (Pss. 93-99), which bear no superscription and may have formed at one time a special hymnal, for they present a certain homogeneity of theme and style, and often include the formula "Yahweh has become king."

7. The Halleluja Psalms, which end with the liturgical invitation "Praise the Lord" (*Halleluja*) and sometimes begin with the call to worship, "O give thanks" (*Hodhu*). Such pieces were meant to be chanted antiphonally (Pss. 105-107; Ps. 111-118, except Ps. 115; Pss. 135-136; Ps. 146-150). The Jewish tradition has set apart Pss. 113-118 as "The Egyptian Hallel," or "Praise" in celebration of the exodus from Egypt, and Pss. 118-137 (or Pss. 120-137) as "The Great Hallel" (used in the ceremonies of Passover).

8. The Psalms of Degrees or Songs of Ascents (Pss. 120-134) overlap the preceding classification. A talmudic tradition assigns these 15 pieces to the Feast of Tabernacles and states that they were chanted by Levites at the head of the 15 steps which led from the court of the women to the court of men. These psalms were originally pilgrim songs (*cf.* allusions to travel in Pss. 121, 122, 132, and to Zion in Pss. 126 and 132).

Principles of Classification.—Many attempts have been made to classify the psalms in a systematic, chronological, or thematic order.

Authors.—Some scholars have in the past proposed to group them by authors, and they have taken the superscriptions (*see* above) to designate authorship, thus: Psalms of David, a Psalm of Moses "the man of God" (Ps. 90), two Psalms of Solomon (Pss. 72 and 127); etc. They point out that 13 of the psalms ascribed to David include prefatory notes which relate them to circumstantial events in the life of the king (Pss. 3, 7, 18, 34, 51, 52, 54, 56, 57, 59, 60, 63, 142). Internal analysis of these poems, however, reveals that they are much later than the 10th century B.C., when

David lived. A number of psalms bear more than one superscription; some refer to "the choir master" (Pss. 39, 62, 77). In Roman and New Testament times, Jews and Christians ascribed all 150 psalms to David; the expression "To so-and-so" designated in all probability not authorship but dedication or the name of an early anthology (*cf.* I Kings 16:20; II Kings 15:15).

Chronological Order.—Other scholars have proposed a chronological order, but there has never been any agreement among specialists on the dates of the individual poems. Moreover, some of the psalms combine fragments of different dates (for example, Ps. 24), and most of them have been revised and expanded through the centuries, very much as the hymns of the Christian Church have been (from patristic Greek or medieval Latin to Luther's German and 20th-century American).

Names of Compositions.—Others have suggested that psalms be classified according to the names of compositions which some of them bear in the Hebrew Bible: Pss. 56-59 are called *miktam*; Pss. 52-55 are known as *maskil*; Pss. 62-68 are entitled *mismor*; still others are merely designated as *shir* (song). Unfortunately, many pieces have no name, and there is no agreement among scholars as to the exact meaning of the name when it appears.

Use and Theme.—Many exegetes of the past generations have grouped the psalms according to their probable use and thematic motifs. It has been recognized, for example, that Pss. 105-106 deal with the history of Israel and that they were used for the celebration of a festival. Thematic motifs, however, are often mixed and sometimes overlapping.

Poetic "Gattung."—Hermann Gunkel was the modern pioneer in the form-critical analysis of the Psalms (1926). From the study of rhythm, strophic structure, chiasmus, key words, and expressions, he has identified five major and seven minor types or genres or *Gattungen* of hymnody:

Major types: (1) hymns, (2) community laments, (3) royal psalms, (4) individual laments, and (5) individual thanksgivings.

Minor types: (1) blessings and curses, (2) pilgrim songs, (3) national thanksgivings, (4) legends, (5) meditations on the Torah, (6) prophetic oracles, (7) wisdom psalms.

In addition, Gunkel showed that most of the psalms fulfill a specific need in the cult, and he sought to determine objective criteria for the reconstruction of this cultic *Sitz-im-Leben* (situation in life). At the same time, Sigmund Mowinkel (1921-24) attempted to relate many hymns and laments to a hypothetical annual Feast of the Enthronement of Yahweh. Later (1949) Artur Weiser sought the cultic milieu of Hebrew psalmody in an equally hypothetical yearly Feast of Covenant Renewal. In all probability, the classification principle enunciated by Gunkel, with some modifications, will stand the test of time.

Classification of Main Psalms.—On the basis of *Gattungskritik* and with due attention paid to thematic motifs and uses, the following classification may be proposed:

1. Hymns of praise: (a) praise of the Lord of nature (Pss. 8, 19, 29, 65, 67, 96, 148); (b) praise of the Lord of history (Pss. 33, 46, 66, 68, 75, 76, 78, 89, 105, 106, 107, 113, 114, 115, 136, 149); (c) praise of the Lord of Zion (Pss. 15, 24, 47, 84, 93, 94, 95, 97, 98, 99, 122, 125, 126, 132, 134, 135, 147, 150).

2. Prayers of crisis: (a) national lamentations (Pss. 44, 60, 74, 79, 80, 83, 123, 137); (b) personal lamentations (Pss. 5, 6, 7, 9, 10, 22, 51, 69, 77, 88, 130); (c) personal supplications (Pss. 3, 4, 13, 35, 38, 39, 41, 42-43, 54, 55, 56, 57, 63, 64, 70, 71, 86, 102, 120, 141, 142, 143).

3. Songs of faith: (a) personal thanksgivings (Pss. 18, 30, 32, 34, 40, 118, 144, 145, 146); (b) prayers of communion (Pss. 11, 16, 17, 23, 26, 27, 28, 31, 36, 62, 103, 116, 121, 131, 138, 139, 140); (c) meditations of Wisdom (Pss. 1, 12, 14 (53), 37, 49, 73, 90, 91, 92, 101, 111, 112, 119, 127, 128, 129).

4. Special psalms: (a) royal hymns (Pss. 2, 20, 21, 45, 61, 72, 110); (b) prophetic oracles (Pss. 50, 81, 82); (c) maledictions (Pss. 52, 58, 59, 109).

Metrical Form.—Rhythm.—English versions do not permit the reader to discover the poetic form of the psalms. Ancient Hebrew poetry in general and psalmody in particular followed highly sophisticated rules of rhythmic and strophic structure.

The basic line is made of two or three cola ("limbs"; see *Prosody*, CLASSICAL), which are symmetrical in the hymns (usually three and three stressed syllables) and asymmetrical in the laments (usually three and two stressed syllables). Lines present various kinds of parallelism of members, as follows:

1. Synonymic, in which the idea is repeated:

In the law of the Lord is his delight,
and in his law he meditates day and night. (Ps. 1:2)

2. Antithetic, in which the idea is repeated by antonymy:

For the Lord knows the way of the righteous,
but the way of the wicked shall perish. (Ps. 1:6)

3. Synthetic, in which the idea is continued from one colon to the next, as in a comparison:

As the hart panteth after the water brooks,
so panteth my soul after thee, O God! (Ps. 42:1)

4. Repetitive-additive (staircase parallelism), in which synonymy and complementariness are combined:

Ascribe to the Lord, ye sons of the gods,
Ascribe to the Lord, glory and power!
Ascribe to the Lord, the glory of his name!
Worship the Lord in the beauty of holiness! (Ps. 29:1-2)

5. Introverted or chiasmic, in which the first word of the first colon is parallel to the last word of the second colon, and the intermediary expressions form a symmetrical pattern, often in the reverse order:

O God, break the teeth of their mouths:
the fangs of the young lions tear out, O Lord! (Ps. 58:6)

6. Mixed, in which any two of the preceding types of parallelism are combined:

The Lord is my light and my salvation:
Whom shall I fear?
The Lord is the strength of my life:
Of whom shall I be afraid? (Ps. 27:1)

Metre.—In order to determine the intrinsic quality of each line, it is necessary to sense the number of accented syllables in each colon and also to consider syntactic units, with links or separations, pauses, and semipauses. A metrical unit may be: (1) a noun in the construct state and the noun to which it is constructed: "the voice-of-the-Lord" (Ps. 29:3); (2) a preposition and a noun: "upon-the-waters" (Ps. 29:3a); (3) a noun and its qualifying epithet or apposition: "upon-many-and-deep-waters" (Ps. 29:3c); (4) sometimes, a verb, especially in the participle, with its direct object: "breaking-cedars" (Ps. 29:5); (5) sometimes, a verb, especially in the so-called "consecutive imperfect," with its subject: "And-the-Lord-shattereth" (Ps. 29:5b). Cola are made of two, three, and exceptionally four metrical units. Thus, lines may be bicola of 3+3, 3+2, 2+3, 2+2, 4+4; or tricola of 3+3+3, 3+2+3, 3+2+2, etc.

Strophe.—The determination of the strophic structure is complex for it is to a certain extent dependent upon the correct analysis of the metre and of the line. Until the discovery of the Ugaritic literature in 1929 (see *UGARIT*), too many critics imposed a symmetrical pattern, by dividing the text of many psalms in false lines, hence were unable to discern the strophes. The proto-Canaanite poetry of Ugarit revealed sequences of bicola exceptionally interspersed with tricola, and since its recovery the study of the poetic structure has been making progress.

A remarkable example of strophic art appears in one of the most archaic pieces of the Psalter, Ps. 29. A prelude (of two bicola, vv. 1-2) develops the thematic motif of "Glory to God in the highest," while a postlude (of two bicola, vv. 10-11) offers a priestly proclamation (v. 10) and a benediction (v. 11) on the theme "Peace on earth." Between these two elements, three strophes of two bicola or tricola each develop the picture of the thunderstorm: gathering (vv. 3-4); bursting forth (vv. 5-7a); dying away (vv. 8-9). Each of the three strophes, in addition, ends with a key word—"splendour" or "majesty" (v. 4b), "fire" (v. 7a), and "glory" (v. 9c)—leaving no doubt in the mind of the singer that the theological climax does not come with the climactic moment of the natural phenomenon but with the singing of the hymn in the heavenly sanctuary.

Musical Instruments.—Rhythmic and strophic structures are

intimately related to the musical aspect of all the psalms, which were originally composed by musicians and were chanted or sung with instrumental accompaniment. At least 17 musical instruments are mentioned in the Old Testament, many of which are also listed in the psalms. They are: (1) idiophones—gold bells on high priest's robe, jingle bells, cymbals, rattler sistrums, gongs or handbells; (2) aerophones or wind instruments—flutes or shepherd's pipes, clarinets or double-pipes, horns (from bulls), short trumpets (ram's horn), the *shophar* (originally, wild ibex horn, often confused with preceding), tubas or long trumpets (made of brass, silver, or gilded silver); (3) membraphones or tuned percussion instruments—drums, tambourines, or tympanons; (4) chordophones or stringed instruments—lyres or ten-stringed instruments, sackbut, trigon, or sambuk (not in the psalms, instruments for music of ill repute), luths or three-stringed instruments, harps or viol or psaltery, perhaps a kind of cithara (guitar) with a box of resonance (of stretched skin on wooden frame).

Modern musicologists are engaged in the difficult task of rediscovering the psalm melodies in Temple and synagogue during biblical times.

Oriental Background.—In both poetic form and musical instrumentation, the Hebrew psalmists inherited skills from the art of their neighbours and predecessors, especially the Egyptians and the Canaanites. The texts of many ancient Near Eastern psalms in Akkadian, Ugaritic, and Egyptian have been discovered, published, and translated. It is now recognized, for example, that Ps. 29 represents a radical adaptation of an Ugaritic (proto-Canaanite) hymn in honour of the storm-god, and that Ps. 104 has been strongly influenced by the Egyptian hymn to the sun-deity by Ikhnaton (Amenhotep IV, c. 1379-c. 1362 B.C.). Differences between the Egyptian prototype and the Hebrew masterpiece, however, reveal the originality of the Hebrew psalmist.

Origins of Hebrew Psalmody.—A rabbinical legend told of King David, roused from his slumbers by the sound of a midnight breeze playing upon his harp; till dawn flushed the eastern skies, David "wedded words to the strains." For centuries both Jews and Christians ascribed the whole Psalter to David. At the end of the 19th century, on the contrary, most critics spoke of a Persian date (538-333 B.C.) and even of the Maccabaeae age (165-100 B.C.) for the majority of the psalms. In the 20th century, the Psalter has been considered to be a collection of poems which reflect all periods of Israel's history, from the exodus (13th century B.C.) to the postexilic restoration (c. 500 B.C.). Several factors played their part in the origin and growth of the psalms:

Miriam, the sister of Moses and a prophetess, may be credited with having composed the first national hymn of thanksgiving, a paean of praise after the victory over the Egyptian Army at the Sea of Reeds. She shouted forth to the accompaniment of timbrel and of dancing maidens (Ex. 15:20-21).

The ark (*q.v.*) of Yahweh, at first connected with holy war (Num. 10:35-36; cf. I Sam. 5-6), was later the cultic sign of real presence in the shrine (II Sam. 6-7), and many hymns were composed for the adoration of Yahweh, present in the sanctuary.

The three seasonal festivals of Unleavened Bread-Passover, Weeks, and Tabernacles (Ex. 34:23) became the occasion for tribal and national gatherings at the shrine, during which elaborate ceremonies of thanksgiving for the fruit of the soil were performed. These included the singing of hymns before, during, and after the performance of the sacred acts, with orchestral music, processions, antiphonal responses, etc.

With the building of the Temple of Solomon in Jerusalem, ceremonial became more and more important in the life of the covenant community. Hymns and laments were composed, edited, and adapted during the whole period of the divided monarchy (10th-8th centuries B.C.) and the last years of the kingdom of Judah.

A few more hymns and national laments were composed during the horrors of the exile in Babylon (587-538 B.C.) and the vicissitudes of the early restoration in postexilic Judaism (from 538 B.C.), and perhaps later (Chronicles, Ezra-Nehemiah).

The influence of the great prophets in the 8th and 7th centuries,

together with the crises which led to the destruction of Israel (c. 722 B.C.) and Judah (587 B.C.), created classes of economically destitute persons who gravitated around the sanctuary and became "the poor" and "the pious," and sang at the Temple ceremonies. Several of these men are responsible for individual laments and supplications.

The teachers of Wisdom, first recruited among the public servants and the foreign diplomats of Solomon and his successors, especially Hezekiah, reflected upon the commandments of their God and wrote poetic meditations which were later incorporated in the services of public worship.

Members of the royal court composed hymns in honour of a new reign, and their expectations of a righteous king received later on a messianic interpretation (Pss. 2, 110).

Religion of the Psalmists.—It is impossible to think of Hebrew psalmody as a product of literary, artistic, or theological homogeneity. Diversity reigns. The present anthology of the Psalter represents expressions of faith which come from many generations and diverse kinds of men. The religion of the psalmists reflects the theology of the entire Hebrew Bible.

The cult of Israel was unique in the ancient Near East, for the act of adoration brought into the liturgical present both the past and the future. Yahweh (*q.v.*), for the psalmists, was not the personified sun or a deified force of fertility. He transcended absolutely the realm of nature. He was held to be sovereign over both the universe and the history of mankind. Hebrew worshippers in their liturgies hailed the serenity of Yahweh and could even afford to laugh about the reality of cosmic evil: "And that Leviathan, which thou hast made, just to play with!" (Ps. 104:26).

Nations engulfed Israel, but the psalmists lived liturgically at the end of time, when history would be brought to its fulfilment and war would be stilled for ever (Ps. 46). They sacramentally saw all the kings of the earth who would worship Yahweh "as the people of the God of Abraham" (Ps. 47). The psalms, more than the oracles of the prophets, created in Judaism its unique sense of the oneness and purpose of history.

Most of the poets who composed the psalms lived under the protection of the sanctuary, but they almost never spoke of the value of sacrificial worship. When they did, they generally spiritualized the meaning of ritual (Pss. 50, 51, 69). This is one of the reasons, surely, for the popularity of the psalms not only among Catholics but also among Protestants and even Quakers. The psalmists' concern in the affairs of the Temple was ultimately centred upon the presence of God in a psychological mode (Pss. 42-43, 84, 139), and stressed harmony in the brotherhood of the worshippers (Ps. 133).

To be sure, psalmists expressed their love for the Law, but they stressed its moral rather than its sacerdotal aspects (Pss. 15; 24:3-6; 34:13-15). Some of them, disciples of the great prophets, discovered even that the scrupulous observance of the commandments of the Law did not give rise to any claim upon the bounty of God. On the contrary, they sensed that a new kind of inward sinfulness might emerge from their awareness of legal self-righteousness (Ps. 19:13-14).

Certain traits appear also in the psalmists' religion which constitute for the modern mind an element of serious limitation. In a number of prayers of confession, of supplication, and of lamentation there may be detected not only an indulgence toward self-pity but also a spirit of oversimplification which tends to associate the poor with the righteous and the rich with the wicked, yet to apply the dogma of special providence in such a way as to associate prosperity with virtue and misfortune with sinfulness (Ps. 37). A tendency also may be seen to separate the insiders from the outsiders and to prepare the way toward sectarianism, to express an attitude of vindictiveness and to manifest *Schadenfreude* (*i.e.*, a malicious joy at the misfortune of another) against the enemies of Israel (Pss. 58:10; 60:8; etc.).

A few psalmists, on the contrary, influenced both by the prophets' "white-hot" religion (Ps. 51) and the existential agony of the Jobian school (Pss. 73, 139), depicted with sharp lucidity their own spirituality and thus became the models of Jewish and

Christian poetry on divine intimacy throughout the ages (Pss. 16, 23, 27, 36; etc.).

It is even possible that this sense of communion was endowed with such a quality of endurance that it presided over the birth of the hope in eternal life (Ps. 73:24b; contrast Ps. 88:5), the overcoming of the fear of alienation (Ps. 22:1), and the expectancy of the heavenly banquet (vv. 25-31). Together with some of the royal psalms (especially Pss. 2 and 110), these songs of faith and communion provided the early church with its first pattern for the needed interpretation of Jesus as the Christ.

PSALTERY, a musical instrument related to the dulcimers and zithers, having gut or metal strings stretched over a flat soundbox. Its outline is characteristically trapezoid, often in the Middle Ages with incurving sides. The psaltery was then plucked with the fingers or with a pair of quill plectra. The strings are all open, none being stopped to give different notes as on a true zither. Probably of Near Eastern origin in late classical times (and inheriting the Greek harp name *psalterion*), the psaltery reached its greatest popularity in the West during the 13th to 15th centuries. No medieval specimen survives. The Russian *gusli* and Finnish *kantele* are rudimentary psalteries, played across the knees. The large Egyptian psaltery, *qanun*, is played with two bone plectra worn in rings on the forefingers. (A. C. Ba.)

PSAMTIK (PSAMMATEK), the name of three pharaohs of the 26th (Saite) Egyptian dynasty (664-525 B.C.). Manetho's Greek transcription of the name, Psammetichos, is often used; Herodotus calls them Psammetichos, Psammis, and Psammenitos respectively. Their predecessors, perhaps of Libyan origin, ruled Sais during the 25th dynasty, first as vassals of the Ethiopian kings of Napata and later, after the Assyrian conquest (671 B.C.), as vassals of Assyria.

PSAMTIK I (Wahibre; 663-610 B.C.) succeeded his father Necho I, after their victory (663) over Tanutamun, the Napatan, when Necho may have been killed. By c. 656 B.C., with the aid of Ionian and Carian mercenaries, Psamtik had subjugated his rivals in the delta, had unified lower Egypt and, with the help of his ally Gyges of Lydia, had expelled the Assyrian garrison. In his ninth year he made himself master of the Thebaid also, installing his daughter as high priestess of Amon at Thebes. During his long reign he restored prosperity to the country, encouraging trade with Greece and reforming the civil and military administration.

PSAMTIK II (Neferibre; 595-589 B.C.), being still troubled by the Napatans, sent a military expedition up the Nile into the Sudan and possibly penetrated far into Cushite territory. On their way back his Greek, Carian, and Phoenician mercenaries left inscriptions in archaic Greek on one of the colossi of Abu Simbel.

PSAMTIK III (Ankhkaenre; 525 B.C.) reigned for a few months only. Defeated by the Persians at the Battle of Pelusium (525 B.C.), he was captured and put to death by Cambyses. See also *EGYPT: History: Ancient Period*.

See Sir Alan Gardiner, *Egypt of the Pharaohs* (1961); F. K. Kienitz, *Die politische Geschichte Ägyptens vom 7. bis zum 4. Jahrhundert v. d. Zeitwende* (1953). (M. S. Da.)

PSELLUS, MICHAEL CONSTANTINE (1018-1078), Byzantine author, scholar, and statesman, whose writings

are of fundamental importance for the understanding of his period, was born in Constantinople. After an excellent education, he became a civil servant; he then entered the imperial secretariat and under Constantine IX (1042–55) he was prominent at court. He was also distinguished for his scholarship and in 1045 became head of the faculty of philosophy in the reorganized University of Constantinople. After an unsuccessful retreat in 1055 to a monastery on Mt. Olympus in Bithynia, he returned to public life and was exceedingly influential during the years 1056–78, particularly under the regime of his friends the Ducas, the last of whom, Michael VII, had been his pupil.

His *Chronographia*, a lively and highly individual history based on his own experiences, is an invaluable source. The *Chronographia* was edited with French translation in the Budé series by E. Renauld, 2 vol. (1926–28); English translation by E. R. A. Sewter (1953). Other works were edited in J. P. Migne, *Patrologia Graeca*, vol. 122 (1864); K. N. Sathas, *Bibliotheca medii aevi*, vol. 4–5 (1874–76); E. Kurtz and F. Drexler, 2 vol. (1936–41). The extensive corpus of his works (some unedited) ranges from philosophy and theology to letters, orations, poems, and incursions into demonology and Chaldean lore. He has been condemned as a timeserving and unstatesmanlike politician but, apart from the encyclopaedic nature of his knowledge which gained him fame in his own day, he also stands out as a distinguished historian and keen philosopher.

Renauld, *Étude de la langue et du style de Michel Psellus* (1920); P. Joannou, *Die Illuminationslehre des Michael Psellos und Joannes Italos* (1956); J. M. Hussey, *Church and Learning in the Byzantine Empire, 867–1185* (1937). (J. M. Hv.)

PSEUDEPIGRAPHIA, literally, books "written under a false name," with the objective of giving them an authority not possessed by the real author or authors, are certain ancient writings, dating from a few centuries before and after the beginning of the Christian era. Among the best known of these are the Books of Enoch, the Assumption of Moses, the Baruch Apocalypses, and the Psalms of Solomon, none of which is included in the Old Testament canon. By convention, books such as Baruch and the Wisdom of Solomon, which are included in the Standard Apocrypha of the Old Testament, are not called pseudepigrapha. See APOC-RYPHA, OLD TESTAMENT.

PSEUDO-CODINUS: see CODINUS, GEORGE.

PSEUDONYM: see ANONYMOUS AND PSEUDONYMOUS LITERATURE.

PSICHARI, ERNEST (1883–1914), French writer and soldier who by his life, writings, and death in action symbolized for many the so-called sacrificed generation which inspired France's spiritual regeneration before World War I. Born in Paris on Sept. 27, 1883, the son of a professor of modern Greek and of the daughter of Ernest Renan (q.v.), he grew up in an atmosphere of liberal intellectualism. In 1902, however, he abandoned his studies at the Sorbonne, and in November 1903 he joined the army, feeling that, for him, the right course lay in rejecting the freethinking, skeptical dilettantism of his family for a life of disciplined action. This personal reorientation, which followed a period of indecision and acute moral and mental stress, was made partly under the influence of Maurice Barrès (q.v.): in the long journey to acceptance of religious faith, of which it proved to be the first step, he was encouraged by his friends, Charles Péguy and Jacques Maritain (qq.v.).

In 1906 he joined the Mission Lefant to the Upper Congo, as a noncommissioned officer. His impressions of the 18 months he spent there, and the meditations inspired by the vastness and solitude of Africa, are recorded in *Terres de soleil et de sommeil* (1908). In 1909 he passed out of the École d'Artillerie with the rank of sublieutenant, and was sent to Mauretania; the discipline of soldiering in the desert acted as a preparation for his later submission to the authority of the Catholic Church. *Les Vœux qui crient dans le désert* (1920), begun in 1910, contains the fragmentary notes and sketches, describing both his travels in Africa and his pilgrimage to God, which formed the basis of his autobiographical novel, *Le Voyage du Centurion* (publ. 1920).

His semimystical philosophy of the call to action and to arms finds its fullest expression in the novel *L'Appel des Armes* (1913).

Psichari returned to France in 1912 and on Feb. 8, 1913, in Paris, he was received into the Roman Catholic Church. This acceptance of religious faith was widely regarded as a deliberate rejection of family tradition, and as an act of reparation for his grandfather's apostasy. He intended to become a priest, and, while garrisoned at Cherbourg (1913–14), prepared himself by a life of increasing asceticism, charity, and spiritual self-examination. But the outbreak of war intervened, and on Aug. 22, 1914, he was killed at St. Vincent-Rossignol, Belg. He thus fulfilled his twofold vocation, to God and to his countrymen, and his death, like his life, was a witness to his faith in the church and in France.

Massis, *Notre Ami Psichari* (1936); W. Fowlie, *E. Psichari: a Study in Religious Conversion* (1939). (He. MA.)

PSILOMELANE, an ore of manganese, is one of a group of hydrated manganese oxide minerals, with very similar appearances and properties, which are difficult to distinguish. They frequently occur in hard black botryoidal or stalactitic masses with a smooth surface, hence the name from the Greek *psilos*, "smooth," and *melanos*, "black." However, they may also be soft and earthy, in which case they are known as wad (q.v.). They are distinctly crystalline and not amorphous as once supposed. The name psilomelane was originally applied to material from Schneeberg, Saxony, which has the formula $\text{BaMnMn}_2\text{O}_{16}(\text{OH})_4$, and should be restricted to this composition. The other manganese minerals of similar appearance are referred to as being of the psilomelane type.

(L. S. RL.)

PSILOPSIDA, a class of primitive vascular plants (phylum Tracheophyta) with only two living genera but several extinct members, present as early as the Silurian Period. Psilophytales, the extinct order of the Psilopsida, is academically interesting as the apparent ancestor of the living order Psilotales and is further considered by many botanists to be ancestral to all other vascular plants. The extinct order takes its name from *Psilophyton*, a fossil from Quebec, Canada, described in 1859 by Sir John William Dawson. It was almost 60 years later before the real significance of this plant was understood. At that time some extremely well-

preserved ancient vascular plants (*Rhynia* and *Asteroxylon*) from deposits of Devonian Age in Scotland were found to resemble *Psilophyton*, and the order Psilophytales was established.

Earlier psilopsids ranged from *Sciadophyton*, a few centimetres tall, and *Rhynia*-like plants, 25–40 cm. tall, to *Asteroxylon* and others, more than a metre high. Unlike the leafy shoot systems of present-day flowering plants, psilopsids had spines instead of true leaves along the stem, and the stems were photosynthetic (based on the presence of stomates and air spaces).

The living genera, *Psilotum* and *Tmesipteris*, are terrestrial or epiphytic. *Psilotum*, an upright, green plant that looks like a leafless shrub about one foot high, is tropical and subtropical

D. W. BIERHORST

PSILOTUM NUDUM GAMETOPHYTE
SHOWING WHITE GROWING TIPS;
TINY WHITE GLOBULES ARE AN-
THERIDIA

in distribution, reaching as far north as Florida and Hawaii; *Tmesipteris*, a pendant green epiphyte, is found in Australia, New Caledonia, New Zealand, the Philippine Islands, and other islands of the South Pacific area. The extinct genera grew in lowlands or were aquatic. *Psilotum* is sometimes grown as a novelty in greenhouses.

Certain features are common to both the living and extinct

(LEFT) PENDANT STEMS OF *TMESIPTERIS TANNENSIS*, WITH FLATTENED LEAVES; (RIGHT) *PSILOTUM NUDUM* SHOOT BEARING SPORANGIA AND TINY SCALELIKE LEAVES

psilopsids. The conspicuous green plant, the sporophyte, consists of an aerial system and an underground rhizome system, both of which repeatedly fork dichotomously, *i.e.*, into two equal branches. No roots are present, the rhizome performing the functions of a root. In *Psilotum* the "leaves" are very small scales, without vascular tissue. In *Tmesipteris* the "leaves" are larger, flattened structures, each with one unbranched midvein.

All psilopsids have a very simple internal organization. The fossil members had smooth stems or stems with spines or small scales. (These "leaves" of the psilopsids may not have had the same evolutionary development as the leaves of ferns and seed plants.) The spore case (sporangium) is three-lobed in *Psilotum* and two-lobed in *Tmesipteris*. The sporangia appear to be axillary in position in reference to the leaves, but research has shown them to be terminal on short branches, the leaves associated with the sporangia being appendages on the branch. The presence of vascular tissue at the base of a sporangium or even in partitions separating compartments in a sporangium supports the concept of terminality of the sporangium.

The vascular tissue is in the form of a slender cylinder occupying the centre of the stem (protostele) in the rhizomes of both living genera. The protostelic condition is true of the ultimate branches in *Psilotum*, whereas in the lower branches of *Psilotum* and in the stems of *Tmesipteris* the xylem occurs in the form of a cylinder of strands surrounding a pith (siphonostele). The phloem forms a cylinder around the xylem strands. The cells of the outer cortex of the stem contain chloroplasts and in *Psilotum* this region accounts for most of the photosynthesis. One interesting feature of stem anatomy in *Psilotum* is the presence of an endodermis. This is a layer of cells surrounding the vascular cylinder in which each cell has lignin deposited in the form of a band in the cell wall. An endodermis is a characteristic feature of roots in all vascular plants but occurs only rarely in stems of seed plants.

Meiotic divisions occur in the sporangia, with the result that spores are formed that have nuclei with half the number of chromosomes found in nuclei elsewhere in the plant. Only one type of spore is formed; consequently these plants are said to be homosporous. Spores are released by the splitting of sporangia along longitudinal slits.

The released spores germinate to form gamete-bearing plants (gametophytes) or prothallia as they are commonly known. These plants are very small, measuring about one millimetre in diameter and several millimetres in length. The gametophytes may grow on trunks of trees or underground. Like the sporophyte, the

gametophyte branches repeatedly. It is devoid of chlorophyll however, and lives a saprophytic existence, aided presumably by an endophytic fungus. These plants are so similar to the underground rhizomes that they can be identified only if gamete-producing structures (gametangia) are present on the gametophyte. Two types of gametangia are scattered over the surface and are intermingled. The egg-producing structure, the archegonium, consists of a sterile jacket of four rows of cells enclosing another row of cells, the lowest one of which is the egg. The sperm-producing structure, the antheridium, is globose and emergent on the surface of the gametophyte; it consists of a jacket of sterile cells enclosing many spermatocytes, which upon release become swimming multiflagellated sperms. To effect fertilization a sperm must swim to the archegonium and down a canal-like passage to the egg (the passage being created by the disintegration of the cells adjacent to the nonmotile egg). After fertilization the first division of the zygote is transverse (perpendicular to the long axis of the archegonium). The outer cell continues to divide and forms the new sporophytic axis. The inner cell gives rise to a multicellular foot, which is in close contact with the gametophyte and presumably functions in the transfer of nutrients from the gametophyte to the young sporophyte. Frequently the young sporophyte axis branches very early during its existence; one branch may become a green aerial shoot while the other becomes a rhizome. The rhizome continues to branch dichotomously, but any of the underground branches may turn up and develop into a green aerial shoot and form leaves and sporangia.

Unquestionably the extinct order Psilophytales is an ancient and primitive group of vascular plants. The Psilotales also are ancient, but some botanists question the assumption that the two orders have a close linear relationship.

PSITTACOSIS, an infectious disease of worldwide distribution, is caused by a virus and is transmitted to man from various birds. The infection has been shown in about 70 different species of birds, but parrots and parakeets (Psittacidae, from which the disease is named), pigeons, turkeys, and a few other species have been the principal sources of human infection.

The disease is also called ornithosis, especially when seen in nonpsittacine birds.

History.—The association between the human disease and sick parrots was first recognized in Europe about 1880, but it was not until 1929–30 that a thorough study of the disease was made. In those years outbreaks of severe cases, attributed to contact with imported parrots, occurred in 12 different countries of Europe and America. During the investigations conducted at that time in Germany, England, and the United States, experimental transmission was accomplished and the causative agent was revealed. Strict regulations followed concerning importation of psittacine birds, which doubtlessly reduced the incidence of the disease but did not prevent the intermittent appearance of cases. The infection was later found in domestic stocks of parakeets and pigeons and subsequently in other species. An increase in the number of cases in Great Britain and the U.S. appeared in 1952, following relaxation of regulations concerning commerce in psittacine birds and an increase in the popularity of parakeets as pets. Infected turkeys have also accounted for many cases. In 1954, a peak year in the U.S., 563 cases were reported, 200 of them related to poultry-dressing plants.

The Disease in Man.—Psittacosis is an acute febrile illness in which some degree of inflammation of the lungs (pneumonitis) occurs, sometimes detectable only by X-ray examination. It tends to be severe in older persons. The duration is two to three weeks, and convalescence often is protracted. Before modern chemotherapy and convalescence often is protracted. Before modern chemotherapy drugs were available the case fatality rate was approximately 20%, but penicillin and the tetracycline drugs reduced this figure almost to zero. Diagnosis can be rendered more accurate by examination of specimens of the patient's blood serum taken early in the illness and during the second or third week. A rise in antibody content in the later specimens, detected by the

complement fixation test in which inactivated (noninfectious) psittacosis virus is used, confirms the diagnosis.

Virus.—The infectious particle, or elementary body, of psittacosis virus is spherical in shape and is one of the largest of the viruses, being 200–300 m μ . (0.0002–0.0003 mm. or .000008–.000012 in.) in diameter. Like all viruses, these particles invade tissue cells of the animal they attack, multiply within the cell, eventually destroying it, and are thus released to invade other cells of the same or another host. Unlike most viruses, those causing psittacosis and related infections are susceptible to chemotherapeutic drugs, as indicated above. Viruses of this type, in addition to occurring in birds, have been found in mice, hamsters, cats, opossums, sheep, and cattle, but as far as is known these do not infect man. A similar virus that is transmitted from man to man directly is that of lymphogranuloma venereum. The generic name *Miyagawanella* has been suggested for this entire group, commemorating the work of the Japanese scientist Y. Miyagawa on lymphogranuloma venereum. An English bacteriologist, S. P. Bedson, during the 1930s contributed basic information on the psittacosis virus, and, in the U.S., K. F. Meyer made extensive studies over several decades on the epidemiologic aspects of the disease.

Transmission and Control.—Psittacine birds apparently acquire the infection in the nestling stage and may become carriers of the virus even though they remain in good health. When such birds are crowded or chilled, as during shipping, or placed under other adverse conditions, the latent infection may be aggravated and become acute. The bird then shows obvious signs of illness and the virus is discharged in excess nasal secretions or in a watery diarrhea. After such infectious material is dried, it readily infects other birds or men, in the form of an inhaled dust. When psittacosis occurs in poultry plants it is seen especially in the personnel exposed to dust or feathers. In a few outbreaks transmission from man to man has occurred, especially from a severely ill patient to nursing or medical attendants, but this is exceptional.

Although it has been impossible to control psittacosis completely on a national scale, some parakeet aviaries have been maintained free of infection by scrupulous care in keeping the birds isolated from disease sources and by practising good husbandry. Chemotherapeutic measures also offer promise. To protect himself and his household, the individual bird owner should avoid contact with sick birds, purchase birds only from known healthy stock, and strive to keep his pet in sound condition.

PSKOV, a town and *oblast* centre of the Russian Soviet Federated Socialist Republic, U.S.S.R., stands on the Velikaya River, at its confluence with the small Pskova stream and 9 mi. (14 km.) above its outfall in Lake Pskov. Pop. (1959) 81,073. It is one of the oldest and historically most important of Russian towns. It is first mentioned in a chronicle of 903 as Pleskov, but there is archaeological evidence for its existence in the 8th century. It acquired early importance as a centre of trade with the Baltic. On the promontory between the Pskova and Velikaya rivers a kremlin (citadel) was established, known as the Krom. The town came under Novgorod as a *prigorod* or suburb and long continued to have close links with its "elder brother." In 1136–37 Pskov attempted to secede from Novgorod, and autonomous government by the town *veche*, or assembly, was granted. The *veche* chose a prince who was responsible for defense. Among the most notable of Pskov's princes was the refugee Lithuanian prince Dovmont, who rebuilt the town's fortifications in 1266. The ruins of his walls still survive. Like Novgorod, Pskov was divided into sectors or "ends," each with its own local assembly and each having part of the Pskov territories. There were six such "ends." As early as the 12th century monasteries were established on the left bank of the Velikaya, which grew into a suburb known as Zavelichye. In 1240 the Teutonic Knights captured Pskov, but after their defeat in 1242 on the ice of Lake Peipus by Alexander Nevski, the 13th century saw Pskov at its height. It is estimated that it had a population of 60,000, and during that century 42 churches were built.

In 1348 Pskov achieved full independence as a republic and

entered the Hanseatic League, but in 1510 it was annexed by Moscow and many of its leading citizens were exiled. In 1571 it was sacked by Ivan the Terrible but, despite this, only 10 years later the town survived a 30-week siege by Stephen Báthory, king of Poland. In 1615 it was besieged in vain by Gustavus II Adolphus of Sweden. The fortifications were renewed and strengthened by Peter the Great, but the 18th century saw a steady decline of the town, accelerated by a disastrous fire in 1710. By 1803 there were fewer than 6,000 inhabitants. In World War II Pskov suffered much damage, but a number of churches and other buildings survived. Notable is the magnificent Cathedral of the Trinity in the kremlin. The present 17th-century building is the fourth on the site, the earliest (wooden) cathedral dating from 957. Modern Pskov is an important railway junction, with lines to Leningrad; Dno and Bologoye; Vilnius (Lithuania) and Warsaw (Poland); Riga (Latvia) and Tallinn (Estonia). There is a large linen industry; also leather working (especially footwear), light engineering, brewing and food processing.

PSKOV OBLAST was established in 1944. Its area is 21,351 sq. mi. (55,299 sq. km.) and its population (1959) 951,866. It lies in the lowland basins of the Lovat and Shelon rivers which flow to Lake Ilmen in Novgorod *oblast*, and of the Velikaya, flowing into Lake Pskov-Lake Peipus (Chudskoe) in the northwest of Pskov *oblast*. Between the two lake basins are the low, morainic Sudoma and Bezhanits uplands. In the extreme south is part of the Valdai Hills. There is everywhere a great deal of surface water in the form of lakes, rivers, and swamps. The climate is continental, much modified by proximity to the Baltic Sea. January average temperatures are about -7°C (19°F) and July averages about 17°C (62°F). Rainfall is about 24 in. a year, with a summer maximum. The *oblast* lies in the mixed forest zone, and much of it is covered by forest of spruce, pine, oak, and birch. Wide areas are in sphagnum peat bog or reed and grass marsh, and flood-plain meadows fringe the many rivers. Soils are usually podzols of low fertility.

Twenty-seven percent of the 1959 population (257,489) was urban, a figure well below the national average. The 14 towns and 5 urban districts are all small, apart from Pskov and Velikiye Luki (58,939). Velikiye Luki was the centre of a separate *oblast* up to 1957, when most of it was incorporated with Pskov. Industries are principally small-scale food processing or linenmaking from local flax, which is a major crop in this and neighbouring *oblasts*. Rye, oats, fodder crops, and potatoes are also grown. The abundant natural pastures are the basis of well-developed cattle raising and dairying, especially for the Leningrad market.

(R. A. F.)

PSOCOPTERA (CORRODENTIA), an order of insects, the best-known of which are book lice, pale flightless insects usually not

BY COURTESY OF ENTOMOLOGICAL SOCIETY OF AMERICA

DEVELOPMENTAL STAGES OF A PSOCID (*AMAPSOCUS AMABILIS*): (A) EGG MASS; (B) SIXTH INSTAR (BETWEEN MOLTS); (C) ADULT FEMALE; (D) ADULT MALE

more than one-fourth inch long, found among old papers, on dusty shelves, or in cereals. Outdoor species, called bark lice, are mostly winged and occur on the bark and foliage of trees, sometimes under stones or in ground litter. The outdoor species are not economically important, but book lice often are a considerable nuisance. Psocid is a general term for any member of the order.

Psocoptera are soft-bodied. The wing venation of flying species is distinctive for its simplicity. The lower portion of the leg (tarsus) is two- or three-segmented, and tail filaments (cerci) are absent; mouth parts are for chewing, with part of the upper jaw usually elongate and chisel-like. Metamorphosis is gradual, and occasionally the gregarious nymphs of outdoor species form conspicuous clusters on tree trunks. Psocids eat molds, cereals, and organic debris.

About 150 species of psocids have been found in the United States, but neither this figure nor the estimate of 1,250 described world species approaches the total number that exist, because the group, now arranged in over 20 families, has been rather neglected by entomologists.

PSORIASIS: see SKIN, DISEASES OF.

PSYCHE, the Greek word for "soul" (see **PSYCHOLOGY**, HISTORY OF: *Greek Psychology*) and the name of the heroine in the story of Cupid and Psyche told by the Latin author Apuleius in his *Metamorphoses* (*The Golden Ass*).

The outstanding beauty of the princess Psyche arouses the jealousy of Venus, who commands her son Cupid to inspire her with love for the most despicable of men. Instead, Cupid falls in love with her himself, but in order to conceal the affair from his mother he does not reveal his identity to Psyche, whom he places in a remote luxurious palace served by bodiless voices. There he visits her only by night in total darkness, warning her of dire consequences if she ever actually sees him. She is overcome with curiosity, however, after a visit from her jealous elder sisters, who insist, in their dissatisfaction with their own commonplace marriages, that her lover is a hideous monster. So the next night she lights the lamp they have given her and discovers that the figure sleeping at her side is the god of love himself. A drop of oil falls on him from the lamp; he wakes, reproaches her, and flies away. After a vain attempt to drown herself, she wanders over the earth seeking him until she falls into the hands of Venus, who imposes upon her impossible tasks which pitying animals help her to accomplish. The final task is to fetch some beauty from Proserpine in the world below, as Venus' beauty is wasting away through nursing Cupid, wounded by the oil dropped on him from the lamp. Psyche's curiosity again proves too much for her: on the way back she opens the box supposedly containing the beauty and is instantly stupefied by its real contents, a deathly sleep. From this she is rescued by Cupid, now recovered, at whose instigation Jupiter makes Psyche immortal and gives her in marriage to Cupid.

The sources of the tale are a number of folk motifs—the invisible lover, the jealous elder sisters, the impossible tasks achieved by the help of animals. The handling by Apuleius, however, conveys an allegory of the progress of the Soul guided by Love, which adhered to Psyche in Renaissance literature and art.

In Greek folklore the soul was pictured as a butterfly, which is one of the other meanings of the word *psyche*. From the Hellenistic period a young girl with butterfly wings is shown in art accompanying Eros (Cupid).

See J. Ö. Swahn, *The Tale of Cupid and Psyche* (1955); M. Grant, *Myths of the Greeks and Romans*, pp. 408-424 (1962). (H. W. PA.)

PSYCHIATRY is that branch of medicine which specializes in the study and treatment of illnesses causing various kinds of behavioural disturbances. These disorders include: disturbances of mood, as seen in depressive states and anxiety; excessive or inadequate affective responses or inadequate social control of emotions; conditions characterized by disorganized thinking and perception, such as phobias, obsessions, delusions, hallucinations;

transient as well as irreversible impairments in intellectual activities; and certain physical disturbances which simulate diseases associated with malfunctioning of body organs.

Psychoanalysis, to be distinguished from psychiatry, is both a particular theory of personality development and functioning and a particular method of psychotherapy used in psychiatry. Strictly defined, psychology is the scientific study of the mind; it is not a medical specialty (see **PSYCHOLOGY**).

Questions of symptomatology and diagnosis, and those concerning etiology, treatment and prevention, are the problems of psychiatry. Sometimes the sufferer's condition is manifested in behaviour that is so grossly inappropriate that the existence of an illness is easily recognized. At other times, the difficulty may be known only to the sufferer. Irrational violence or the striking immobility of severely depressed persons are obvious pathological conditions. On the other hand, states of apprehension, obsessive thoughts and unreasonable fears may exist for prolonged periods without recognition. In the latter instance, the conditions become known only through the subjective reports of the ill, or when the symptoms intrude upon ordinary routine activities and force a general awareness of a mental illness.

In explaining the genesis of behavioural disorders, modern psychiatry emphasizes the patient's genetic predisposition; the influence of anatomical, physiological and biochemical processes; and the determining effect upon the nervous system of the recording of the person's ongoing series of life experiences, beginning with the prenatal period and extending through childhood experiences in the family to the environmental and cultural pressures. To the psychiatrist, the sum of these factors determines personality. A human being's personality is recognized as his characteristically recurring patterns of behaviour in response to life experiences, to and with other persons. (See **PERSONALITY**; **BEHAVIOUR**.)

I. HISTORY

A. EARLY HISTORY

Many modern scientific concepts regarding psychiatric disorders are derived from the historical past. References to mental disorders in early Egyptian, Indian, Greek and Roman writings show great insight, but for the most part the philosophers, physicians and theologians who contemplated and wrote about the problems of human behaviour regarded psychiatric illnesses as a reflection

of the displeasure of the gods or as evidence of demoniac possession. Only a rare few realized that behavioural problems were not separable from physical illnesses and that the sufferers should be treated humanely rather than exorcised, banished or punished. Although progress was slow in banishing the belief in supernatural causes, as early as 360 B.C., some Greek priests supplemented their incantations and exorcisms for the mentally disturbed with recommendations for kindness and physical and recreational activities such as walking, riding and listening to soothing music.

A significant advance toward scientific understanding of mental disorders occurred in the 6th century B.C. when the Greek healers turned to observation and interest in experimentation. At this time, Alcmaeon made the first dissection of the human body and observed the connection of sense organs, such as the eye and the ear, to the brain. Searching for the seat of reason and of the soul, Alcmaeon decided that they were located in the brain.

Shortly after Alcmaeon reported on his experimentation, the problem of mental disorders gained the attention of Greek philosophers. Empedocles spoke about the significance of emotions and the possibility that love and hate were the fundamental sources of change in behaviour. Plato incorporated concepts of Empedocles in his consideration of the role of Eros in the personal and social life of man. This medical and philosophical thought was not recaptured until Sigmund Freud (*q.v.*) presented his theories and clinical studies in the late 19th century (*see below, Modern Schools: Psychoanalytic School*).

Hippocrates (fl. 400 B.C.), a sensitive, perceptive observer of clinical phenomena, described many mental disorders found in modern times, including psychosis after pregnancy, delirious states associated with infections such as tuberculosis and malaria and the acute confusion which follows severe hemorrhage. He flatly rejected the idea that mental disturbances were caused by the intervention of the gods or by possession. He also took an unequivocal position concerning the legal rights and responsibilities of the mentally disturbed. Athenian law recognized the rights of the mentally disturbed in civil affairs, but gave no special consideration to the mentally disturbed when they became involved in capital crimes. Through the vast respect accorded him, Hippocrates was able to provide this consideration. In the Athenian courts, if it could be proved that the person on trial suffered from a condition which Hippocrates designated as paranoia, the court would appoint a guardian for the accused.

Hippocrates classified mental disorders into three categories: mania, melancholia and phrenetis. His descriptions reveal many of the classical symptoms which are recognized in epilepsy, mania, melancholia and paranoia. To Hippocrates, hysteria was a mental disease, but it was limited to women. As he saw it, hysteria was caused by the wandering of the uterus through the body and symbolized the body's pining for the production of a child; he thought that marriage was the best remedy for hysteria.

Hippocrates and his followers were the first group of physicians who approached mental illness scientifically. Their understanding of mental disorders emphasized natural causes, clinical observations and brain pathology. They were the first to describe and examine empirically the clinical materials of psychiatry. In establishing a movement toward the biological study of mental illness, Hippocrates challenged and won people away from the theological interpretations. Many physicians after Hippocrates contributed substantially to psychiatry, notably Asclepiades of Bithynia, Aulus Cornelius Celsus, Aretaeus, and Soranus. Soranus, in his instructions for the treatment of disturbed patients, prescribed the use of tact and discretion; he stated that the patient's attention must be tactfully directed to his difficulties; he advised the physician to observe the mental patient's tolerance to sedation and warned of the need to supervise the patient through his period of convalescence.

The high point in medical thought of this period was reached in the work of the Roman physician Galen (2nd century A.D.), who, through a scientific approach to the study of the anatomy of the nervous system, drew attention to the role of the brain in mental functioning. He discovered that the existence of a symptom did not necessarily mean that the organ or the part of the body

which expressed the symptom was the affected portion. As a consequence of his experimental work and his studies of mental disorders, Galen developed a theory of the rational soul as divided into an external and an internal part. The external part consisted of the five senses. The soul's internal functions were imagination, judgment, perception and movement. On the basis of his experimentation, Galen concluded, as Plato had thought and Aristotle had denied, that the brain, not the heart, was the seat of the soul. His observations had shown him that compression of the heart affected only the function of the arteries. Galen rejected the idea that hysteria resulted from the wandering of the uterus about the body, but he considered it to be caused by a local engorgement of the uterus.

In the period following the death of Galen, primitive thinking about mental illness re-emerged. Witchcraft and demonology dominated medical thought of medieval times and continued to exert an influence into the 19th century. However, beginning with the 16th century, signs of scientific questioning began to appear again. Among the physicians who challenged demoniacal explanations of mental disturbances were Paracelsus, Agrippa and Johann Weyer. Beginning with Francis Bacon in the 17th century, a number of philosophers, recognizing that the functions of the mind were a part of their concern with the natural order of the universe, began to exert an effect on medical thought. Notable among those who contributed to the modern science of psychopathology were Descartes, Hobbes, Locke, Condillac and Hume.

B. 19TH CENTURY

1. Humanitarian Movement.—Paralleling the reappearance of scientific questioning and the development of medical science was an improvement in the public attitude toward the mentally ill. These combined factors resulted in the establishment of mental hospitals and in more humane treatment methods. The humanitarian movement received its initial impetus through the efforts of the French physician Philippe Pinel (1745-1826), who after the French Revolution was placed in charge of the Bicêtre, the hospital for the mentally ill in Paris. Under Pinel's supervision, a completely new approach to the handling of mental patients, as well as a new concept of mental hospital operation, was introduced. Chains and shackles were removed from the patients. In place of dungeons, the patients were provided with sunny rooms and permitted to exercise on the hospital grounds. The reforms which Pinel sponsored and their gratifying results placed France in the forefront of psychiatry.

In England, through the efforts of William Tuke and his son Henry, aided by the Society of Friends, York Retreat was opened (1796) for the humane care of the mentally ill. In the United States, an energetic and courageous New England woman, Dorothea Dix (*q.v.*), between 1841 and 1881 carried on a campaign to arouse the people and the legislators to an awareness of the inhumanities which prevailed in all of the country's mental hospitals. Not only was Miss Dix the leading spirit in improving the care of the mentally ill in the United States, but she also helped in promoting the reform movement in Canada and in Scotland. The modern mental hospital in North America and in western Europe aims at providing a friendly, encouraging, therapeutic atmosphere. The hospital staff attempts to provide a variety of activities designed to help the patients regain mental health. While there is still a large gap between practice and theory in many hospitals, the modern mental hospital is moving in the direction of the "open-door" policies initiated in England. The term open-door symbolizes the trend away from the locked ward toward freedom of the patient to move about the hospital and recognition of the therapeutic effects of a sheltered, supportive environment where all the staff help the patients and patients help each other to health. (*See also MENTAL HEALTH.*)

2. Biological Movement.—Along with humanitarian reform in hospital practice and treatment methods during the late 18th and the 19th centuries, there was a resurgence of medical and scientific interest in psychiatric theory and practice. Great strides were made during this period in establishing a scientific basis for the study of mental disorders. A long series of observations by bril-

liant clinicians in France, Germany and England culminated in 1883 in a classification of mental disorder by Emil Kraepelin (*q.v.*). His integration of a mass of descriptive clinical data into meaningful symptom categories was a major contribution to psychiatry, and his classification system served as the basis of all subsequent nosologies.

Rapid advances in studies of anatomy, psychology, pathology, chemistry and bacteriology led to the expectation of discovering specific brain lesions for the various forms of mental disease. While this search did not attain the results desired, the scientific emphasis was productive in that it did elucidate the gross and microscopic pathology of many brain disorders which produce psychiatric disability. In addition, the research effort illuminated the role of infectious and metabolic disturbances in the production of mental diseases. One of the notable achievements of this period was the discovery of *Treponema pallidum* (*Spirochaeta pallida*), the organism causing syphilis, as the basis of the brain pathology producing general paresis. Other discoveries were the causation of pellagra psychosis in a vitamin deficiency and the recognition of delirious reactions caused by malnutrition and pernicious anemia. Significant observations also were made on the cellular changes in the brain which accompany the presenile and senile psychoses, and a number of pathological conditions associated with mental retardation were identified. The advances made in the 20th century toward establishing the biochemical correlates of mental disturbances and in developing the tranquilizing agents represent the moving fringe of the earlier search for etiological specificity in disordered body organs and systems.

3. Psychological Movement.—Certain of the major psychotic states, notably schizophrenia and manic-depressive reactions, frustrated the effort to find in cellular pathology the principal causative agent of mental disease. Other explanations were needed for the many puzzling aspects of these conditions, and these explanations emerged in a wave of psychological viewpoints, beginning with the study of hypnosis in relation to hysteria. The arrival of Franz Anton Mesmer in Paris in 1778 dated the beginning of broad scientific interest in psychological factors as influencing or altering human behaviour. Advancing the belief that the distribution of a universal magnetic fluid in the body was the basis of health and disease, Mesmer opened a clinic in Paris where he treated all kinds of diseases, including hysterical paralysis (*see HYSTERIA*), in a ceremonial setting in which he "magnetized" the patients by applying to their bodies iron rods treated with various chemicals. Mesmer's therapy was a group method of treatment; he moved among his patients touching each of them with his hand and waving a wand over them.

Mesmer's own personal success was short-lived, and he was branded a charlatan. His work was studied by a committee of the Academy of Sciences whose members included Jean Sylvain Bailly, Benjamin Franklin, Lavoisier and LeRoi. The committee was unable to find any evidence of animal magnetic fluids, but it was impressed with the results produced by Mesmer's touching of the patients. It advised against the use of mesmerism and warned of potential dangers from harmful imitations. Outside France the recommendations of the academy went unheeded, and mesmerism spread throughout the world. A French magnetizer, Charles Poyen, introduced séances of magnetism in the United States from which the watchmaker P. P. Quimby (*q.v.*) obtained his first conceptions of faith healing and successfully treated Mary Baker Eddy for hysterical paralysis. Use of mesmerism as an anesthetic during surgery was advocated by several physicians, but this practice passed quickly with the introduction of nitrous oxide and chloroform.

The first physician to be attracted by scientific curiosity to the serious study of mesmerism was the English surgeon James Braid (*q.v.*), who showed that the condition resulted solely from suggestion, and introduced the term hypnosis. After Braid, the scientific study of hypnosis lagged until a French country doctor, A. A. Liébault (1823–1904), resumed interest in the subject and learned to use hypnosis for the induction of sleep. Liébault subsequently made wide use of hypnosis in his medical practice, and he also taught the technique to the French physician Hippolyte

Bernheim, the English neurologist J. M. Bramwell and the renowned French neurologist Jean Martin Charcot (1825–1893).

Questioning the view that psychological factors could cause hysteria, Charcot conducted, at the Salpêtrière hospital in Paris an extensive and detailed study designed to determine the organic factors associated with the condition. On Feb. 13, 1882, Charcot presented a report of his findings to the Academy of Sciences. He convinced the academy members that the phenomena of hypnosis were manifestations of abnormality and that the characteristics of the hypnotic state could be observed only in patients with hysteria. The same academy that earlier had condemned research on animal magnetism was thus won to a new point of view. Charcot's success prepared the way for the harvest of psychological insights that followed. Among his many students was Freud.

Charcot's views were not accepted by all French physicians, however. Bernheim, who was professor of medicine at Nancy, vigorously challenged Charcot's conclusion, maintaining that the phenomena observed at the Salpêtrière took place only when conditions of suggestion were set up by the hypnotist. He stressed the study of the process of suggestion and the characteristics of suggestibility, and rightly claimed that the latter were not restricted to hysterical persons. Bernheim's work, apart from providing a new perspective on hypnosis, had other implications; some psychiatrists have regarded it as the first attempt to evolve a general understanding of human behaviour. Developing out of his studies, for example, were new questions concerning the legal responsibility of criminals and the causes of criminal behaviour; Bernheim, by advancing the belief that mechanisms of suggestion underlay the endless variety of normal and abnormal behaviour, challenged the concept that the will was the agent of crime and evil. Along with Charcot, Bernheim put to final rest the persisting concern with demoniac possession.

Pierre Janet (*q.v.*) also studied hysteria and furthered the acceptance of psychological causation. Recognizing the neurotic components of hysteria (fixed ideas and inner conflict with reality), Janet insisted upon psychological treatment for the condition. His psychotherapy was founded primarily on the use of persuasion and of techniques for altering the patient's environment. The work with hypnosis and hysteria opened the door for further recognition of the psychoneuroses. *See also* HYPNOSIS; FAITH HEALING.

C. MODERN SCHOOLS

Freud took the first steps toward providing the theoretical structure upon which much of modern psychiatry rests. Adolf Meyer (*see below*) had a prominent role in the development of modern psychiatry through his pluralistic and interactional concepts of human behaviour; he drew attention to the multiple biological, psychological and social factors that influence personality. Both Freud and Meyer were greatly aided in the construction of their theories by knowledge of the work of the great English theoretical neurologist John Hughlings Jackson (*q.v.*).

Drawing from the genius of Charles Darwin and Herbert Spencer, Jackson set forth an evolutionary theory to explain the function and development of the nervous system. In the development of his theory, Jackson drew from his extensive and careful clinical observations of epilepsy and other diseases of the brain. He concluded that the functions of the nervous system were integrated at progressively more complex levels, with mentation, the highest level of function, located within the cerebral cortex. Jackson viewed the symptoms accompanying impaired brain function as representing both the disappearance of the most recently acquired functions of the brain, and the reappearance of earlier and more primitive functions that had become submerged during the evolutionary process. According to Jackson, when injury to the brain produced a permanent defect in the functioning of the nervous system, in addition to symptoms caused by loss of function and symptoms representing re-emergence of more primitive functions, the organism also produces another type of symptom to compensate or substitute for the loss. Jackson's theoretical position inherently postulates that the understanding of any behavioural disturbance is dependent upon knowledge of the progressive

development of a particular type of behaviour in a given organism as well as knowledge of the presentation of such behaviour in other living species. Such assumptions are basic for both the psychoanalyst and psychobiologist.

1. Psychobiological School.—The psychobiological school of psychiatry, established by Adolf Meyer (*q.v.*), represents in broad outline the theoretical structure of the general field of modern psychiatry. Meyer, who moved to the U.S. in 1892 from Switzerland, received his training in Zürich. He emphasized that the understanding of human processes and the problems of human behaviour lie in the utilization of knowledge from biology, psychology and sociology. The explanation of the total personality requires study of the physical attributes of the individual as well as the many social, cultural and emotional influences to which he has been exposed. Meyer stressed the importance of early parental influences in the development of the personality of the child and conceived of mental disturbances as progressive habit formations. The techniques he developed for psychiatric examination are the basis of all those used in English-speaking countries. Meyer insisted that understanding of maladaptive behaviour required a comprehensive study of the life history of the individual, tracing the development of the personality through each progressive and unfolding stage to the present life situation. To Meyer, the individual was both a product and a victim of his life experiences. Meyer emphasized that each individual personality had its assets and its liabilities. The existence of faulty habit patterns implied possibilities of teaching healthy ones. To the psychiatrist he appealed for careful study of the development of symptoms, and cautioned that symptoms should not be attributed to a specific cause. Meyer's orientation departed markedly from that of theorists and practitioners who explained mental phenomena solely on a physical basis.

The weakness of Meyer's psychiatry lies in its failure to work through the study of intrapsychic processes and their origin in family life; recognition of the importance of these forces represents some of the most significant thought to the psychoanalytic school. The psychobiologists emphasize that psychiatric disabilities are reactions rather than disease processes with established courses.

2. Psychoanalytic School.—The psychoanalytic movement originated in the perceptions and meticulous clinical observations of Freud. After studying with Charcot, Freud returned to Vienna, where he was associated with Josef Breuer (*q.v.*) in studies of neurotic patients under hypnosis. Freud and Breuer observed that their patients tended to relive earlier life experiences, which could be associated with the symptomatic expression of the illness. When the sources of the patients' ideas and impulses were brought into consciousness during the hypnotic state, the patients showed improvement. Although the collaboration was proceeding well, Breuer became disturbed by the responses which the patients made to him (a phenomenon later defined by Freud as the transference relationship) and discontinued the study; Freud pursued it alone.

Observing that most of his patients talked freely without being under hypnosis, Freud evolved the technique of free association of ideas. The patient was encouraged to say anything that came into his mind, without regard to its assumed relevancy or propriety. Noting that patients sometimes had difficulty in making free associations, Freud concluded that certain painful, anxiety-ridden (traumatic) experiences were repressed from conscious awareness. Freud noted that in the majority of the patients seen during his early practice the events most frequently repressed were concerned with disturbing sexual experiences. Thus he hypothesized that anxiety was a consequence of the repressed energy (libido) attached to sexuality; the repressed energy took expression in various symptoms that served as psychological defensive mechanisms.

Freud later modified his concept of anxiety. His new concept regarded anxiety as the emotion generated by the threat of some fearful occurrence or of impending danger. In later years, Karen Horney (*q.v.*) and other psychiatrists extended Freud's concept of a threatening event leading to the arousal of the anxiety. The

more recent theories of anxiety included not merely feelings of fear, guilt and shame consequent to sexual fantasies that the person regards as reprehensible; anxiety is conceived also as resulting from the arousal of fantasies of aggression and hostility and from fear of loneliness caused by separation from a person on whom the sufferer is dependent.

Freud's free-association technique provided him with a tool for studying the meanings of dreams (see DREAM AND DREAMING: *Theories of Dreams*), slips of the tongue, forgetfulness and other mistakes and errors in everyday life. From these investigations he was led to a new conception of the structure of personality: the id, ego and superego. (1) The id is the reservoir of drives and impulses derived from the genetic background and concerned with the preservation and propagation of life. Freud regarded the drives resting in the id as the prime sources of the sexuality and aggressive impulses that are needed to perpetuate the race and to satisfy the biological needs for food, water, oxygen and warmth. The impulses of the id are seen as operative beyond conscious awareness. (2) The ego (*q.v.*), in contrast to the id, operates in the conscious and preconscious levels of awareness. It is the portion of the personality concerned with perception, cognition and executive actions. (3) The third portion of the personality structure Freud called the superego. In this rests the individual's accumulated ideals and values and the mores of his family and society; the superego serves as a censor on the ego functions.

In the Freudian framework, conflicts among the three structures of the personality are repressed and lead to the arousal of anxiety. The person is protected from experiencing his anxiety directly by the development of various adaptive psychological patterns known as defense mechanisms (*q.v.*). They are learned through the family and the cultural influences to which the growing child is exposed. They become pathological when they interfere with the capacity of the adult to pursue the satisfactions of living in a society. The existence of these patterns of adaptation or mechanisms of defense are quantitatively but not qualitatively different in the psychotic and neurotic states.

One of Freud's fruitful contributions was his concept of transference. In the course of his work with his patients, Freud became aware of the deep attachments they formed for him. Learning that the patients of other analysts reacted similarly, he concluded that these emotional attachments represented a repetition of the relationship the patient previously had with his parents or their substitutes. The love or hatred which the patient felt for his parents and which he unconsciously projected to the analyst influenced the patient's capacity to make free associations. By objective treatment of these responses and the resistances they evoked, as well as by bringing the patient to analyze the origin of his feelings, Freud concluded that the analysis of the transference and the patient's resistance to its analysis were the keystones of psychoanalytic therapy. Psychoanalytic therapy contrasts with all other forms of psychotherapy in its emphasis on transference. Recognition of the transference relationship has been of major importance to the entire field of psychiatry, however, and to medicine generally.

Freud described the development of personality as a psychosexual evolution that begins at birth and continues through childhood. In the framework of Freud's libido theory, the personality develops through a series of stages: oral, anal, urethral, oedipal and genital. The implication of these stages to personality development is that various body zones have the capacity for pleasurable sensation. As the child grows, the centres of body gratification pass progressively from one area to another. (See also PSYCHOANALYSIS.)

3. Interpersonal School.—The U.S. psychoanalyst Harry Stack Sullivan (*q.v.*) stressed the careful study of the interaction between the developing child and his parents and his later relations with others as providing a more significant operational method of understanding human behaviour than that of the libido theory. Sullivan's conceptions, which represent a blend of psychoanalysis and psychobiology, are represented in the interpersonal school of psychiatry.

4. Psychosomatic Medicine.—The term psychosomatic medi-

cine does not properly refer to a school in psychiatry; rather it describes the directed interest of a growing group of psychiatrists who, in close collaboration with other colleagues in medicine, are concerned with the study of reactions to anxiety as expressed through physiologic disturbances. In these instances responses of bodily organs rather than inappropriate symbolic behaviour are the defenses against threat. Psychosomatic disorders comprise not only the "organ neuroses" noted in early psychiatric classifications but also many other physiologic disturbances known to be precipitated by emotional stress. Bodily reactions to stress take expression in cardiovascular disorders; respiratory ailments such as certain forms of asthma and attacks of hyperventilation; gastrointestinal disturbances leading to belching, flatulence, anorexia, obesity, constipation and diarrhea; migraine and tension headaches; pelvic pain; dysmenorrhea; dyspareunia (in women, difficult or painful coitus); and impotence and frigidity. Psychosomaticists also study and treat the stress-induced responses contributing to modifications of the diabetic metabolism, the neurodermatoses, gastric and duodenal ulcers and ulcerative colitis.

Psychosomatic medicine is concerned not only with describing the nature of conflict- or stress-induced physiologic disturbances but also with defining the conditions under which disturbances of internal organs take place. Much emphasis is placed on the fact that emotional problems aggravate all illness and that denial of the existence of an emotional disturbance provokes greater disability.

In determining proper treatment, the psychosomaticist is interested in learning the kinds of situations and thoughts that produce personality disturbances. This knowledge is essential to understanding and preventing many conditions, such as the hallucinations and delusions that some patients have when they are deprived of sight during cataract operations. The gynecologist and obstetrician seek information about the patient's feelings concerning contraceptive practices, artificial insemination, therapeutic abortion and other emotionally laden areas of medicine. The surgeon can be assisted by knowledge of the patient's fears of mutilation or disfigurement; a patient's negative response during convalescence or unwillingness to undertake rehabilitative measures may be a consequence of his emotional attitudes to physical illness. All these conditions, as well as many others, require the attention of either a psychiatrist working in the medical service of a hospital or with a group of physicians who have understanding of psychosomatic interaction.

II. DIAGNOSIS AND CLASSIFICATION OF MENTAL DISORDERS

A. DIAGNOSIS

The psychiatric diagnosis is based on examination of the patient and history of his illness. Information is obtained concerning possible hereditary influences, the patient's physical maturation and his emotional and social development, taking into account experiences in both the family and community environment. Physical as well as neurological examinations are made and, when indicated, are supplemented by psychological tests (see **PSYCHOLOGICAL TESTS AND MEASUREMENTS**) and other special examinations such as electroencephalographic or biochemical and serological tests. Together these procedures provide data upon which the psychiatrist makes his diagnosis and formulates the determinative factors that explain the reaction patterns of his patient.

1. Symptomatology.—The actions of the mind cannot be isolated and separated into independent functions, such as the senses, memory, imagination, reason, desire or perception. Nor do the symptoms of mental disorders represent disease of a particular area of the brain. Psychiatric symptoms are expressions of loss or impairment of some function or of failure in development of that function. Loss of function may arise from psychological conflict, or it may occur secondary to a structural disturbance of the brain. For example, a defect in memory could be the consequence of an inherited defect; it could result from a blow to the head or from a growing brain tumour; or it could be the expression of a psychological conflict.

For most psychiatrists, anxiety and its control represent the

central problem in psychopathology. Although many stressful experiences and conditions give rise to both fear and anxiety, these emotional reactions are usually differentiated. In general, fear is temporary and is directly related to some external event. Anxiety, in contrast, is aroused by any threat to the person's wholeness or his self-concept. It is a pervasive sense of apprehension or tension, the source of which is not consciously recognized. Anxiety has its antecedent in the tensions of early infantile life, and it is aroused in the growing child and in the adult in relation to actual or fantasied interpersonal conflicts.

When fear or anxiety is aroused, the person attempts to adapt and bring about a state of equilibrium or condition without tension. Rightly or wrongly, in actuality or in fantasy, the anxious person expects to receive an unfavourable reaction or estimate of his personal worth or conduct from someone whom he respects or whom he considers to be in authority. Through learning, the expressions of anxiety tend to be disguised or converted into various socially adaptive mechanisms; thus, most people are unaware of anxiety or of the circumstances that provoke it. When the person becomes anxious, however, the anxiety interferes with his capacity to recognize, evaluate and manage properly the situations associated with it. The ability to learn or profit from experience is impaired and capacity to adapt to new situations is limited because only a restricted range of stereotyped and repetitive responses is available.

Hostile and aggressive attitudes, expressed both overtly and covertly, are among the commonest psychiatric symptoms. Such impulses are often repressed in the psychological sense; by reaction formation they may re-emerge as pathologically excessive solicitousness and gentleness. Sometimes the hostile impulses are projected onto other persons; this is a common occurrence with paranoid types, who ascribe their destructive impulses to others. It should be noted that aggressive trends are utilized constructively in certain sports and work.

Pathological disturbances of motility are recognized in the behaviour of hyperactive, nonproductive persons. In these conditions, there may be a tremendous drive to action or to speech, often leading to what is designated as a stream or flight of ideas. Constant repetition of speech or of body movements is an expression of a motility disturbance underlying a compulsive drive. Various mannerisms may occur in which the person grimaces, repeats gestures, shows peculiar types of gait or repeats meaningless words or phrases.

Healthy affect, or the feeling tone of a person's life, is evident in ability to make controlled and variable responses to daily life experiences. Affectivity penetrates and colours the psychological life and influences the thought and action of every person. Disturbances of affect may lead to disturbances of consciousness, motility and intellect. Affective state can modify a person's judgment and ideas to the extent of distorting his capacity to evaluate reality, and thus it may lead to delusional and hallucinatory thinking.

Pathological elation, a condition seen in the manic behaviour of some psychotics, is an affective state of abnormal confidence and enjoyment. It is also recognized with certain brain syndromes such as general paresis, brain tumours and multiple sclerosis. A less frequently observed pleasurable state is that of ecstasy. The opposite of elation and ecstasy is depression, varying from mild downheartedness and indifference to feelings of despair and hopelessness.

Disturbances in perception and thought are seen in hallucinations and illusions, phobias, obsessional thinking and delusions; in apparently disconnected or loose associations; and in unusual retardation or flights of ideas.

(See also **DEPRESSION [IN PSYCHIATRY]**; **HALLUCINATION**; **MANIA**; **PARANOID REACTIONS**; **PHOBIA**; **SCHIZOPHRENIA**.)

2. Predisposing and Precipitating Factors.—Diagnosis of a psychiatric illness requires consideration of the predisposing and precipitating factors. These include a wide range of situations and conditions: hereditary background; effects of previous illnesses; presence of physical defects; use of drugs such as alcohol and narcotics; existence of nutritional and vitamin deficiencies;

vocational, sexual or economic stress; and exposure to particular kinds of privation. Numerous studies have been and are being conducted to determine the precise correlates of mental disorders.

Heredity.—The exact role of heredity in the development of mental and emotional disorders is still a matter of conjecture. Evidence indicates that certain inborn errors of metabolism transmitted through recessive genes underlie some forms of mental retardation. Based on studies of the incidence of schizophrenia among persons with various relationships to a schizophrenic patient, F. J. Kallmann postulated that schizophrenia is transmitted by recessive genes in the form of a predisposition; the schizophrenic reaction develops when a biologically vulnerable person is placed under particular stress. Kallmann reported a concordance rate for schizophrenia of 86% of identical twins and of only 14.5% among fraternal twins and siblings. Criticisms of attributing mental disorders solely to genetic factors rest largely upon the potentiality that parents have for transmitting their emotional difficulties to the next generation through the prolonged social learning that takes place in the course of family living.

Age.—Mental and emotional illnesses tend to make their appearance at certain ages. Adolescence, the middle years and senescence are associated with periods of major physiological changes and psychological stresses involving problems in family, vocational and social roles. During adolescence, the incidence of psychotic reactions rises rapidly. The young person must deal with the stresses arising from sexual maturation, the decisions to be made in the selection of a vocation and the conflicts that ensue in becoming emancipated from parents and assuming independent status. For women, the middle years are particularly critical, as they terminate the opportunity and hope for child bearing. This period also often brings emotional stress with the departure of children from the home and the need for the mother to find satisfactions in new roles and activities. Men at this age often have emotional problems associated with waning sexual energies and failure to attain to aspired goals. In old age, psychiatric disability tends to be precipitated with the mounting limitations of physical incapacities, the loss of satisfactions from work life and the emptiness of the retirement years, the loneliness that comes through the death of old friends and associates and other stresses. (See also GERONTOLOGY AND GERIATRICS.)

Sexual Factors.—While sexual behaviour in itself does not appear to be a source of mental disturbance, attitudes toward sexual acts and emotions aroused in relation to sexual strivings contribute to psychiatric illness or influence the content of the illness. No sexual act is in itself a cause of mental illness, but the unremitting anxiety and guilt that some persons experience over such acts may be a cause. (For varying attitudes toward sex practices, see *SEXUAL BEHAVIOUR: Human Sexual Behaviour*.)

Married persons appear to be considerably less susceptible to mental disorders than the widowed, single and divorced, but marriage in itself will neither cure nor prevent mental illness. In a marriage from which no sense of security is derived, the emotional disturbance of a partner may be aggravated.

No specific psychiatric disability is aroused by pregnancy or the postpartum period. The mental disturbances which occur sometimes with pregnancy and childbirth arise from the emotional significance these events have to the mother. For a woman who is psychologically unprepared and emotionally immature, the bearing of a child may arouse unconscious and repressed conflicts toward her own parents and siblings. Approximately one-half the psychiatric reactions to pregnancy are schizophrenic; the other half are manic-depressive or psychoneurotic.

Alcohol.—Alcohol plays an important role in producing mental disease; there is a direct correlation between the amount of alcohol consumed in a community and the incidence of observed alcoholic psychoses. Underlying the habituation to alcohol usually is a primary personality disturbance. The same personality defect occurs with narcotic addiction.

Disease and Injury.—In western countries where the diet generally is adequate, cerebral impairment resulting from vitamin and other nutritional deficiencies is seen most often as a second-

ary complication in the elderly or seriously psychotic. However, the longevity achieved in most western populations has greatly heightened the problem of mental debility stemming from the cerebral maladies of old age (see below, *Brain Disorders*).

Congenital or acquired physical defects often play an important role in creating personality disturbance. Acceptance of one's body and its acceptance by others represent a nuclear issue in the development of a secure personality. Children born with defects or children whose physical characteristics are unattractive to their parents often develop self-disparaging and self-defeating attitudes. The consequence is frequently a defect in the ability to make social adaptations that may be severe enough to cause psychiatric disability. Adults who suffer a disruption of their body image through injury, surgery or illness also are liable to personality disturbance. Among the commonest precipitants of psychiatric disability are head injuries, which may lead either to organic brain syndromes or to neuroses.

At one time overwork was considered a cause for mental illness. In the modern view the person who works long hours and excessively does so in order to fulfill a personal need—to reduce anxiety or as an outlet for energy or creativity. Work is also a means of maintaining human contacts in an otherwise withdrawn person. When a breakdown does take place in relation to vocation, usually a disruption of some important human relationship is threatened or has taken place. No evidence exists that mental efforts, in the absence of anxiety, produce psychotic or neurotic illness.

B. CLASSIFICATION

Kraepelin's classification system for mental disorders, established in 1883, was in general use until 1917, when the American Psychiatric association introduced the system that became the basis of that recommended in 1948 by the association in the fourth edition of *Standard Nomenclature of Diseases and Operations*. This classification system is more comprehensive and more flexible than the earlier schemes, and it also can be applied to the practice of psychiatry in general hospitals, in out-patient clinics and in private office practice, as well as in mental hospitals. According to this system, mental disturbances may be classified into three general categories representative of physical and psychological pathology: (1) acute and chronic brain disorders caused by or associated with impairments of brain tissue function; (2) mental deficiency; and (3) psychogenic disorders having no clearly defined physical or structural change in the brain. The psychogenic disorders, the major group, comprise the psychoneuroses, the majority of psychotic reactions, psychosomatic disorders and personality disorders.

1. Brain Disorders.—*Acute.*—Acute brain disorders are organic brain syndromes, usually temporary, from which a patient recovers. Although they generally involve reversible impairments in brain function, some of these disturbances may result in permanent changes in brain tissue, which can be detected by modern micropathological techniques. For the most part, they are the result of a serious disruption of the metabolism of the brain, particularly its capacity to metabolize glucose, its basic energy source. The symptoms of these disorders have been known under the general term of delirium (*q.v.*).

Delirious reactions are characterized by varying degrees of disturbances in consciousness and impaired awareness of surroundings. Some persons have the capacity to develop these reactions more readily than others, and the form and content of the delirium tend to be related to the underlying personality and the life experiences. The delirious person may show variable states of cloudiness, bewilderment, periodic somnolence, stupor or, in the deepest stages, coma. Usually, in states of confusion or bewilderment, the sufferer is anxious or apprehensive. Upon being questioned, he shows impairment in his ability to grasp meaning and to comprehend correctly the environment as to place, time or person. He is disoriented. Along with delusions, some persons experience frightening hallucinations.

Deliria are commonly associated with febrile illness, toxic states, metabolic disturbances (such as uremia, pellagra or pernicious anemia), states of cardiac decompensation and trauma following

head injury. The best known of the acute brain syndromes is the delirium tremens of the alcoholic.

Chronic.—Chronic brain disorders result from a permanent impairment of cerebral tissue and are characterized particularly by disturbances in memory, judgment and affect (any experience of emotion or feeling). General paresis was once the most prevalent of these conditions, accounting for 8% to 10% of the patients committed to public mental hospitals. The use of penicillin for the treatment of syphilis greatly reduced the incidence of this disease.

At mid-20th century, the most frequently encountered chronic brain disorders are those suffered by large numbers of elderly presenile persons or those that occur as a consequence of cerebral arteriosclerosis in later life. Both these conditions are most prevalent in the U.S. and in western European countries which have expanding aged populations. In the U.S. chronic brain syndromes due to senile and arteriosclerotic psychoses account for approximately 40% of the hospitalized mentally ill. (See also DEMENTIA.)

2. Mental Deficiency.—This, the second large category of mental disorders, is defined as an impoverishment in intellectual competency which results either from an innate fault in the individual's developmental potentiality or from arrested development. Thus, the mentally defective person is not equipped with intellectual capacities, judgment, social skills and foresight that are possessed by the average person. (See MENTAL DEFICIENCY; RETARDED CHILDREN.)

3. Psychogenic Disorders.—Psychogenic disorders are defined as conditions whose causes or origins are not clearly traceable to a physical cause or to structural damage of the brain and the nervous system. These disorders include the major psychoses, such as the schizophrenic, paranoid, manic-depressive and involuntional reactions; psychophysiological (psychosomatic) reactions; psychoneurotic reactions; and personality disorders. They are characterized by varying degrees of personality disturbances, ranging from catastrophic to minor interference in interpersonal relations. Distinctions are easily made between the psychoses and psychoneuroses when the symptoms are well-defined, but these illnesses can be very difficult to differentiate at their early stages or in the borderline states. Symptomatology most commonly is the basis of distinction, but the disorders are also distinguished on legal and social grounds.

Psychosis.—The diagnosis of psychosis usually implies a greater severity of personality disturbance than that occurring in psychoneurosis. In the psychotic person the inner emotions and experience are so disturbing that he is frequently unable to carry on ordinary social functions. The psychotic has a limited capacity for differentiating his own subjective experiences, *i.e.*, describing what he is, has actually observed, tried or known; his capacity to interpret and respond to his environment therefore is gravely impaired. In other terms, he is unable to deal with reality; he creates his own special environment in which his perceptions are distorted or falsified in the form of delusions or hallucinations. The thought processes of the psychotic are often so disorganized that his thinking appears disrupted and irrational. (See also PSYCHOSES.)

Psychoneurosis.—Unlike the psychotic, the psychoneurotic presents personality traits which are regarded as a socially acceptable adaptation against anxiety. In psychoneurosis, the inner experiences do not bring about a gross disturbance of external behaviour. The neurotic has the ability to maintain contact and good testing of the external environment. Although his thinking may be restricted or distorted by his overvalued and limited ideas, he does not suffer delusions and hallucinations. Moreover, he is not excessively withdrawn socially, and he usually retains his interest in the people and the world about him.

The question as to whether a neurosis may become a psychosis has been argued for years, but there is no certain or definitive knowledge. Psychiatrists who consider the psychotic reaction as a disease process usually reject the idea that progression can occur. On the other hand, most psychiatrists recognize a large number of borderline states, particularly with schizoid personalities, where the social adaptation of the patient is very precarious.

The multiplicity of neurotic symptoms that certain patients suffer the ambivalence they demonstrate, their disturbed psychosexual life and their poorly developed self-concept have given rise to the classification by some psychiatrists of "pseudoneurotic schizophrenics." (See also NEUROSES.)
